COOK BOOK
PART THREE - CAL TSS, the CAL Time-sharing System

Chapter 1 - What CAL TSS is and how it runs
1.1 Introduction to CAL TSS
1.2 Sample session at the console: Log on, creating a text file with the editor, printing it on the line printer, log off

Chapter 2 - User Subsystem

2.1 Command processor
2.2 File editor
2.3 Line editor
2.4 SCOPE simulator
2.5 Debugger
2.6 BASIC
2.7 RCPL
etc. printer, reader, gettape, dumpape, etc.

Chapter 3 - System architecture

3.1 Files
3.2 Directories
3.3 Processes; Subprocesses (F-return)
3.4 Capabilities and C-lists
3.5 Operation/calling the system
3.6 Event channels
3.7 System resources: control and accounting
3.8 Disk processes

Chapter 4 - System Actions

Chapter 5 - I/O Interfaces
Preface

Use of this manual

CAL TSS is a time-sharing operating system available to users of the Computer Center. Chapter 1 contains folksy bits of information to help the novice get acquainted with CAL TSS and get a feeling for its capabilities and usefulness. Chapter 2 tells how to talk to the system via the command processor and various subsystems currently available; parts of it will be essential to every user. Chapter 3 contains sufficiently detailed information about system concepts and structure to be of interest to a system programmer and can probably be skipped by the casual user without dire consequences. Chapter 4 gives the details of system-implemented actions which a user may invoke in code he writes. These actions may be considered as extensions to the 6400 hardware and are of interest mainly to subsystem-implementors and machine-language programmers. Chapter 5 gives details on the I/O interfaces which would allow a user to establish his own printer driver, for example.
CHAPTER 1 - WHAT CAL TSS IS AND HOW IT RUNS

1.1 INTRODUCTION TO CAL TIME-SHARING SYSTEM

CAL TSS is a large-scale, general-purpose time-sharing system written by the Computer Center staff to run on a CDC 6000 series machine with RCS. The broad design goals of the system are:

1. to support up to 756 simultaneous interactive users at teletype-compatible terminals with fast response times for simple interactions, low system overhead, and good access to various hardware facilities;

2. to provide a file system allowing many files to reside permanently in the machine and to provide a very general, powerful framework within which such files can be accessed, shared, and protected;

3. to provide a system environment in which a large number of user-oriented subsystems can be developed and run;

4. to make possible a guaranteed response time for some subset of the users of the system;

5. to utilize efficiently the hardware represented by the Computer Center’s 64003 system.

CAL TSS is called "large-scale" because it is in primary control (i.e., does not run under another system) of the computer, which is a large-scale machine. It is a "time-sharing" system because a large number of users at terminals may have programs active simultaneously and may each command responses from their programs on a time-scale of a few seconds. Finally, it is called "general-purpose" because the terminal user is not restricted to some particular programming language or set of programming languages; he may, in fact, program in machine language if he so desires. In general terms, the system provides facilities for the interactive user to:

1. create files, preserve them in the system, retrieve and destroy them;

2. manipulate text files with a text editor;

3. process files with a number of subsystems provided, including
a. a SCOPE simulator, giving access to all the facilities of
   the SCOPE system, including RUN Fortran, COMPASS, SNO-
   BOL, etc.;

b. a BASIC processor;

c. BCPL (a low level systems programming language);

4. prepare and run his own subsystems which may interact with his
teletype and other subsystems;

5. access the card reader, line printer, tape drives, and display
   console;

6. give access privileges for his objects selectively to other
   users if he so desires and obtain privileges of access to
   objects of other users who wish to grant it.

When the terminal load on CAL TSS is low, another system facility will
process a subset of the batch jobs normally processed by the SCOPE
system. Other facilities can be implemented as determined by the needs
of the computing community, the programmer time available, and the
capacity of the hardware.

The structure of CAL TSS and the methods of using it are extensively
described in the subsequent pages of this document. Here are briefly
described concepts which all users of the system will have to deal
with, whether his aim is to run Fortran or to implement a language
processing system, whether his aim is to run FORTAN or to implement a
language processing system of his own.

Figure 1.1 indicates the hardware configuration of the current 6400B system, on which CAL TSS is run. An exact understanding of all the boxes and their interconnections is, fortunately, unnecessary, but a brief description of the memory hierarchy will make dealing with the system more understandable. Note first that a file is the basic entity for storing information in the system; code ready for execution on the central processor and text ready to be fed to a language translator are both maintained in files.

Figure 1.2 represents as a pyramid the different storages present in the hardware. As the figure indicates, storage at the bottom is slow and cheap and big, while storage at the top is fast and expensive and, at present, small.

The disk, at the bottom of the pyramid, contains all the files which are accessible to the system without outside intervention such as mounting a tape or reading a card deck.

At the top, central memory contains the actively executing code of one process. As the central processor is switched from one process to another, the code is swapped between CM and ECS. Thus, ECS must contain the code files for all processes currently active on the system.

Part of any file which is being manipulated by one of the active processes (an open file) may be in ECS or on the disk at the discretion of the process concerned. It may explicitly ask the system to maintain parts (blocks) of the file in ECS by attaching them and may dismiss blocks by detaching them. When a process accesses part of a file which is currently in ECS, the information is delivered immediately. Access to part of a file not in ECS causes the process to be blocked (stop running) until the system is able to bring the required information in from the disk. A process may, by attaching a block of a file in advance of its need to use it, improve its real-time processing speed at a cost of using more ECS.

Within this context, some of the terms with which every user will eventually become acquainted are now defined.

**User profile:** When someone makes arrangements to utilize CAL TSS, a body of information is recorded with the Computer Center business office which identifies him and describes his funding and access to

---

1 The normal user at a terminal may consider all his interactions with the system to be carried out under the auspices of his own private process.
various system facilities. This information is called the user profile.

Log_on/Log_off: When a user attracts the attention of CAL TSS from a terminal, if his user profile and funding are in good shape, he is logged on. This is a procedure which gives him access to his own objects and such system objects and resources as his user profile allows. System resources, such as memory space, are reserved for his use at this point and may be charged against his account. When the user logs off, the resources are released and charging ceases.

File: As already noted, files are the basic entity for storing information in the system. Program code ready for execution as well as input to and output from language processors reside in files.

Directory: Directories are special objects which control access to other files, directories, and other system objects. Directories also provide the mechanism for associating symbolic names ("print names") with the objects controlled by the directory.

Permanent_disk_space: An amount of space determined by the user profile is permanently reserved for a user's files. It is the only system resource tied up by a user who is not currently logged on and is charged for continuously. It is controlled by the user's permanent directory.

Temporary_disk_space: When a user logs on, space on the disk, as determined by his user profile, is reserved to hold the temporary files he may need while running, such as output files and compiler scratch files. This space is controlled by his temporary directory.

Process: A process may be thought of as an organizational entity within the system which ties together certain code from files and other resources necessary to "carry out a task" or "run a program". CAL TSS creates a process for each user as he logs on the system. His process looks like a 6400 central processor with somewhat less than 32K of memory; the full range of 6400 CP instructions is available to it. In addition, the user's process is able to manipulate files and certain other system-defined objects in a general way. It is delivered already equipped with some code which can, for example, communicate with the user at his teletype. The private process created for the user is given access to his permanent directory (among others), thus giving him access to his files without giving access to other users.

Fixed_ECS_space: Various data relevant to the state of a process are kept in ECS by the system, as are certain other objects germane to its functioning. Also, the control information for open files is kept in ECS. Because the system has no facility for keeping such information on the disk, it is kept in what is called fixed ECS space. The amount
of fixed ECS which is set aside for a given user's process is determined by his profile when he logs on.

**Swapped ECS space**: Files and directories which are currently in ECS at the request of a user's process are kept in what is called swapped ECS, so that the system can free ECS space if it needs to by swapping the files out to the disk. The amount of swapped ECS available to each user is also determined by his profile at log in time.
Desiderata

1) don't echo passwords
2) squelch "waiting for space" messages
3) inter teletype communication
4) 'space obtained message'
5) change addkey to addlock
6) fix ETELL ("Test of ETELL" !??! ?)
7) units on Charge, Logout

CAL Time-Sharing System
Status and Information, 13 August 1971

Availability

CAL TSS is currently available weekdays from 2-6 PM. There are 8 teletypes available for general use during these hours in Rooms 225 and 227 Campbell Hall. For information about connection of additional teletypes, contact Vance Vaughan (see below).

Documentation

The fundamental document for users is the Introduction to CAL TSS, available from the Computer Center librarian. Other documentation is also available at the library, but it is spotty and users should consult with someone on the TSS staff before acquiring any.

TSS Consultant

A member of the TSS staff is available in Room 225 Campbell Hall, ext. 2-5008, from 2-3 PM every weekday except Wednesday. He will answer questions, demonstrate the system, help new users through initial sessions, etc. Users unable to reach the consultant should contact Vance Vaughan, 207 Evans Hall, ext. 2-5823. He is there Thursdays from 1-2 PM, or by accident, or by appointment. Leave a message in the main Computer Center office, 239 Evans Hall, ext. 2-0851 to arrange an appointment.

Getting help, reporting problems, etc.

Sections 1.7 and 1.9 of the Introduction to CAL TSS give procedures and information for diagnosing and understanding problems encountered when using the system. If the user's teletype is dead, or has gone crazy, he should first consult those sections. They may solve the problem, or be irrelevant, or give some such helpful advice as 'call a system programmer' or 'the teletype is down or the system is down'. If they are irrelevant, or say to contact a system programmer, or something like that, contact the TSS consultant (not the regular programming consultant). When the diagnosis is that the teletype is down or the system is down, the user should call the shift supervisor, (64)2-3043, and explain the problem. If the system is down, he will give information about when it will be up. If the system is up, there is some problem with the teletype or the line. The user should contact the person responsible for the maintainence of the teletype (Computer Center teletypes are maintained by Charles Cuffel, ext. 2-4403).

Complaints and suggestions:

These should be made to the TSS consultant. The TSS staff is especially anxious to get feedback on the documentation. Corrections to content and suggested style modifications are both welcome.
INTRODUCTION TO CAL TSS

Preface

1. General concepts

1.1 Access to CAL TSS
1.2 Files, directories
1.3 Login, logout
1.4 Command Processor, subsystems
1.5 Names, objects, name spaces, access locks, access keys
1.6 Command processor name space, BEAD name space, SCANL, PERMDIR, TEMPDIR, OWN.KEY, null key, PUB.KEY
1.7 SERVICES, BEAD GHOST, errors
1.8 Space control (what to do about 6, ?, ? errors)
1.9 'WHO' and PANICS, or how to untangle a console and how the user stops something he wishes he hadn't started
1.10 A note on the Line Collector (how to erase mistakes)

2. Examples

2.1 Use of BASIC, not keeping permanent files
2.2 Creation of a permanent disk file to be kept for future sessions:
   2.2.1 future access 'automatic'
   2.2.2 future access 'manual'
2.3 Access to permanent disk files
   2.3.1 Using BASIC on the file from example 2.2.1
   2.3.2.1 Selective access to permanent files
   2.3.2.2 Making all the user's permanent files available to all subsystems
2.4 SCOPE Simulator: a simple interactive FORTRAN program
2.5 SCOPE Simulator: an interactive SNOBOL program using a file from a friend's directory
2.6 Login problems illustrated

3. Subsystem summaries

3.1 EDITOR
3.2 BASIC
3.3 SCOPE
3.4 SERVICES and the BEAD GHOST
PREFACE

This document is intended to provide inexperienced users with quick and easy access to many CAL TSS facilities. It is not intended to be logically complete or fastidiously accurate.

The first part gives a brief description of the logical structure of the system as seen by the user. The second part is a collection of examples of some useful interactions. The examples provide a cookbook approach which may be adequate for some users, and it is hoped that the section on general concepts will be helpful in easing the user into productive and flexible use of the system. However it is doubtful that these pages will answer all questions or transform someone with no previous experience into a proficient user without some work.

Fortunately, one need not be an expert to use the system. One of the advantages of interactive systems is that the user can "try it and see if it works" without incurring a prohibitive cost in money or time. Thus, a light reading of this document should be more than enough to prepare the user to start experimenting on the system itself. Of course, having assistance from someone who knows CAL TSS is very helpful. But in the absence of expert advice, going back and forth between the examples, the console, and the description of general concepts is hopefully a reasonable route to expertise.

The third section gives brief summaries of the subsystems available on CAL TSS. These summaries are not intended to teach people how to use the subsystems. Rather, they are intended as convenient "crib sheets" for people who already know how to use them.
1.1 Access to CAL TSS

To use CAL TSS, one must satisfy two requirements. The first is to make arrangements with the Computer Center accounting office, or a TA, or some such authority who has time to dispense. He will provide the name of a permanent directory which will pay for use of the system, and a password, which will verify the right to use that directory. The second is to have access to a teletype (or other teletype compatible terminal), connected to the 6400 B system. It is assumed that the reader has access to such equipment and knows how to operate the equipment itself. Below are noted a few useful features of keyboard input to CAL TSS:

a) input lines are terminated by the RETURN key (no line feed)
b) typing CTRL-Q erases the previous character entered
c) typing CTRL-Y erases all characters in the current line
d) typing CTRL-I skips to the next tab boundary (cols 11, 21, ...)

1.2 Files and Directories

Files are system-maintained objects in which a user can keep information (source code, programs, data, etc.). In particular, when a user is not active on the system, virtually all the information he wants to keep is stored on the disk in files. Directories keep track of the names and locations of all the files in the system, plus various other information. Each user has his own directory which keeps track of his own personal files and contains information pertaining to him. This directory stays on the disk when the user is not active and is called the user's permanent directory to distinguish it from other directories which are described later.

1.3 Login, logout

The process of making contact with CAL TSS is called LOGIN. The user tells the system he is present by typing CTRL-SHIFT-P on the console. The system then starts to construct the machinery necessary to give him access to his files and to the various subsystems available to manipulate files. Nominal amounts of system resources are reserved for him. This nominal amount is sufficient to run a small BASIC program or to use the EDITOR to modify a text file. The console responds by asking the user to name his permanent directory and to prove that he is authorized to use it by giving the password.

A temporary directory is then created to hold the files that come and go as he uses the system. The console asks him to name his temporary directory. Since this name will be used globally across the system, it must not be the same as someone else's temporary directory (if it is
the same name as another's, the user is then asked to choose a different name. The appearance of the Command Processor signals successful completion of the LOGIN procedure.

The temporary directory and any files which it owns will be destroyed when the user finishes using the system and logs out. It is easy to logout: simply get into the Command Processor and type 'LOGOUT' (see examples).

Note that once the user has successfully logged in, he starts being charged for the resources necessary to be active on the system. This charging will stop only after LOGOUT (not when the console is turned off).

1.4 Command Processor, subsystems

When the LOGIN procedure is completed, the user will be talking to the Command Processor. The Command Processor does not do many things for the user itself, rather, it accepts commands to set up various subsystems to work for him. Some standard subsystems which are always available on the system are introduced in Table 1. A user may also code and call (through the Command Processor) his own subsystems. The exact method of doing this is not described here.

<table>

</tbody>
</table>

The Command Processor and all the subsystems print some character at the beginning of the line when they are ready to accept a command. This is called a prompt character. A table in section 1.9 shows the different prompt characters for all the system-provided subsystems. After the Command Processor prompts, the user might tell it
EDITOR INPUT

intending to edit a file called 'input' (the ! at the beginning of the line was typed by the Command Processor, not the user). A general example of the form of commands accepted by the Command Processor is:

!command param param ... param

where command and param are strings of characters separated by spaces. How the Command Processor turns the characters at the console into internally meaningful information is a long story, which is introduced next.

1.5 Names, objects, name spaces, access locks, access keys

When the user types

!EDITOR INPUT

to the Command Processor, 'EDITOR' and 'INPUT' are examples of what are called names in this document. The handling of both these names makes use of the concept of name space. The trick is to turn a string of characters into some internal form which will give access to a file or a subsystem. A name space can be thought of as a dictionary which translates a string of characters (name) into the required internal form. There are several different types of internal forms all of which are referred to as objects. Files and directories are examples of objects. A directory contains the names of objects and also information about those objects. Thus, one form of name space is a sequence of directories to be searched in turn for the given names.

Another important concept in changing names into objects is that of an access key. A given name in a directory may be shared by having an access lock attached to it. In order to get access to the named object, an access key must be presented along with the name. Access locks not only control whether or not access is permitted, but also what kind of access is permitted. Thus, a given file name in some directory may be protected with two different access locks such that when it is looked up with one key, the file may only be read from, while it may be read, written, or destroyed if it is locked up with the other key.

The most common form of name space is a sequence of pairs (directory, access key). The scope and power of a given name space are determined by what directories are searched and what access keys are used.

There are several different name spaces attached to each user, and different ones are used in different circumstances.
1.6 **Command Processor name space, BEAD name space, SCANL name space, PERMDIR, TEMPDIR, PUBLIC, CWN.KEY, null key, PUB.KEY**

The first parameter typed to the Command Processor is looked up in the command processor name space (see Table 2). **PERMDIR** is a name used to refer to the user's permanent directory. **TEMPDIR** is a name used to refer to his temporary directory. **PUBLIC** is the name of a directory which contains the names of all system-provided subsystems. For example, it contains the name 'EDITOR'. If the user has just typed:

```
!EDITOR .INPUT
```

the Command Processor is guaranteed to find the name 'EDITOR'. Having found the object named EDITOR, the Command Processor assumes that the object is a file which it can use to construct the EDITOR subsystem. It proceeds to do this. Note that if a file named EDITOR were in the user's temporary directory, the Command Processor would find that file because it searches **TEMPDIR** first. It would then try to start up a subsystem constructed from the user's file, which is fine if the file contains the user's own private version of the EDITOR. Otherwise, an error results. It is always best for the user to know what he is doing before he tries it.

The interpretation of the parameters after the first one is dependent on the subsystem being called; each subsystem specifies the name space it uses to evaluate parameters. The three possible name spaces are shown in Table 2. The **BEAD name space** is an old form left over from previous incarnations of the system. It is being phased out. The **SCANL name space** is initially as shown in Table 2, but the user may modify it to suit himself.

Much of the complexity of the name space situation stems from considerations about the sanctity of permanent files (owned by the permanent directory) and the reliability of subsystems. Consider the nature of the files in the user's permanent directory as opposed to the nature of the files in his temporary directory. Many subsystems use temporary or scratch files which are not of interest to the user. These files come and go in **TEMPDIR** without troubling the user. They automatically disappear when he logs out. Free access to these files is essential to the operation of the various subsystems. Presumably it is no great loss if a subsystem runs wild and a temporary file gets clobbered. **PERMDIR**, on the other hand, gives access to the user's permanent disk files. The user would be justifiably annoyed to discover that one of his files had been used as a scratch file by some subsystem. There is no automatic backup of these files. If some subsystem has access to a user's files and uses one for scratch or goes wild and destroys files, he is in trouble. His files are gone, and it will be monstrously inconvenient and expensive to recover them. Therefore the system does not automatically allow access by subsystems to the files in the permanent directory. If the user trusts all the subsystems he is going to call, there are ways he can grant those subsystems access to files in **PERMDIR** (see 2.2-2.3), but great caution...
is advised. It is as though those files were the only copy of the information.

One difference between the various name spaces is indicated by the access key used when looking in the permanent directory. The null_key can only be used on one's own directories (PERMDIR, and TEMPDIR in most cases of interest). It gives unrestricted access to any file in those directories. OWN_KEY is the user's personal key which was created along with his permanent directory. It is unique to him, unless he gives it away. The user may grant access to a given file in his permanent directory from name spaces less powerful than the command processor name space by attaching an access lock matching OWN_KEY to the file. The access may be restricted (to read only access, for example) by turning off suitable 'option bits' in the lock one puts on the file (see examples). PUB_KEY gives read only access to the files in the PUBLIC directory.

Now it may be clear that there must be at least two name spaces. On the one hand, unrestricted access to the files must be possible, otherwise the user might not be able to do something with his file that he wants to do. On the other hand, there must be name spaces which keep unreliable subsystems from wreaking havoc. The existence of more than two name spaces is an unfortunate historical accident.

The existence and use of the name spaces is complicated by compatibility features for subsystems following the conventions of an extinct early version of the system. For both 'old' and 'new' subsystems, the command name is looked up in the command processor name space, but the processing of the subsequent parameters varies.

Old subsystems have all parameters looked up in the BEAD name space. During execution, they may request further objects from the Command Processor, which are also looked up in the BEAD name space. All existing subsystems are being converted to the new conventions as quickly as possible.

New subsystems have their parameters looked up in the command processor name space. During execution, they may request further objects in two ways. If the subsystem makes up the name of the object, it is looked up in the SCANL name space. Objects may be obtained from the command processor name space only if the user types in the name from the TTY. Thus, in either case, permanent files are protected from unruly subsystems and from accidental use as scratch files.
1.7 SERVICES, BEAD GHOST, errors

For use of CAL TSS beyond the trivial, a knowledge of these two special subsystems is required. SERVICES and the BEAD GHOST are similar to normal subsystems, but are actually just new 'hats' donned by the Command Processor appropriate to the occasion.

SERVICES is a general utility subsystem allowing manual manipulation of files, directories, etc. The main reason for removing this function from the Command Processor proper is to minimize the number of reserved words which may not be used as names of user subsystem ('SERVICES', 'LOGOUT', etc.).

Unlike SERVICES, which is troublesome because it must be called, the BEAD GHOST is annoying because it appears without being called. The BEAD GHOST is the system debugger and its appearance is prompted by some error. Whenever a subsystem makes a mistake in dealing with some object or some part of the system, error processing is initiated. Some errors are handled automatically by various subsystems along the way,

---

1 methods for altering SCANL from the console are available.
2 The BEAD NAME SPACE really occurs in several forms. This is the most common form. Other forms are not of crucial interest and are not described here.
and the user isn't even aware of them. Many are reported to the console by a given subsystem to indicate that they were asked to do something illegal or impossible (the Command Processor is an outstanding example of this). Some represent unforeseen circumstances for which no remedial procedures have been provided (called 'bugs' for short). They are reported to the console by the BEAD GHOST in hopes that the user will know what to do (like complain to a system programmer). Currently, only class 6 errors ("6,n,m ERROR") should be reported to the console by the BEAD GHOST under normal circumstances. Other appearances of the BEAD GHOST should be reported, along with all the relevant console printout, to the system staff.

Class 6 errors mean that the resources reserved for the user have become inadequate for the task being performed. When they occur, the user must either obtain additional resources or abort what he was doing, which introduces the next topic.

1.8 Space Control

CAL TSS has several types of storage for which there is currently no automatic algorithm for sharing the available space among the users. The only positive thing to be said for the scheme described below is that it is better than simply handing out space until it is all gone and then letting the system grind to a halt (or crash).

<table>
<thead>
<tr>
<th>TYPE</th>
<th>NOMINAL</th>
<th>MODERATE LIMIT</th>
<th>MAXIMUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) swapped ECS space (highest type)</td>
<td>7000</td>

<td>not concurrently controlled</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4) temporary disk space (lowest type)</td>
<td>not concurrently controlled</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When a user logs on, he is allocated the nominal amount of space of each type. A command is available to obtain space in excess of this amount. If a user requests an amount of space larger than what is currently available he is put into a queue waiting for someone to release space. If the request is for more space than the moderate limit, he is put in a special queue which prevents more than one user at a time from being "very large" in any particular type of space.

There is currently no mechanism to force a user to release space once he has it. Several mechanisms tend to prevent space hogging. First, whenever a user returns to the Command Processor, he is automatically
reduced to nominal. Last, a user who has space over the nominal in some category is not allowed to get more space in that or any higher category without first releasing his space and going to the back of the queue.

The space command works as follows and may be typed to the BEAD GHOST or to SERVICES:

```
SPACE p1 p2 p3 p4
```

$p1$ through $p4$ are the amounts of swapped ECS space through temporary disk space, respectively, that are desired. The following algorithm is executed for each parameter starting with $p4$:

- **if** $=-1$ : space of this type is released to get down to nominal if possible
- **if** $=0$ or not typed (trailing parameters): ignored
- **if** $>0$ : 1) If space above the nominal for that type or higher type has been obtained, error.
  2) If parameter is higher than maximum permitted for this type, error.
  3) If parameter greater than moderate limit, enter very large queue.³
  4) If parameter less or = nominal, no further action.
  5) Otherwise, accumulate this type of space until the amount this user has is up to the size of the parameter, waiting in queue if necessary.³

There are two different starting points from which the user may find himself requesting space:

1) He is about to call a subsystem and knows in advance how much space it will require: enter SERVICES and request the required amount of space and then go back to the Command Processor and call the subsystem. The request has to be big enough - see below!

2) A subsystem he has called runs out of space and makes a class 6 error which invokes the BEAD GHOST: if he has not already requested space, the user may do so now with the space command. After he has gotten the space, he types RETRY (not RETURN) and the subsystem will resume. If he already has space, there is no way for him to save himself - he must type

³ A message will print if the space is not immediately available - a panic (see 1.9) will remove the user from the queue if he would rather not wait.
PURGE, which aborts whatever work the subsystem may have done for him, and start over in the Command Processor.

1.9 'WHO' and PANICS (how to untangle a console and how the user stops something he wishes he hadn't started)

WHO is a request that may be typed at the console to determine which subsystem is in control. PANICS are a way of interrupting whatever is going on if the user has somehow lost control. PANICS come in two flavors:

MINOR PANIC (or PANIC for short) - hold down the CTRL and SHIFT keys and simultaneously type P to send a minor PANIC;

MAJOR PANIC - hold down the BREAK key for at least three seconds to send a MAJOR PANIC.

The difference between a PANIC and a MAJOR PANIC is that subsystems may handle PANICS on their own if they wish to, but a MAJOR PANIC always invokes some arm of the Command Processor.

The remainder of this section gives three procedures covering different cases of console problems, plus a table telling how to recognize and/or dismiss subsystems.

PROCEDURE I covers how to approach a console initially.

PROCEDURE II tells what the user does if he is already logged in and using the console but has either forgotten what he was doing or the console stopped responding the way he expects it to.

PROCEDURE III is for those times when the user has started something that he wants to stop (e.g., the EDITOR is printing 2000 lines because he mistyped something or his BASIC program has been computing silently for an ominous length of time, etc.).

Sometimes the relevant procedure has a happy ending and the user can continue. But, alas, the procedure may suggest that the console is down, or the system is down, or there is a bug in the system. The user can frequently distinguish between a sick console and a sick system by seeing if. other consoles in the area are operating. If they are, it looks like the console is sick. If they aren't, it looks like the system is. The current procedures for reporting troubles of this nature should be available from some other sources. They are not included here because they are in a state of flux.
PROCEDURE I - a user is just approaching a console to try to establish contact with CAL TSS

- Make sure the console is on and is connected to CAL TSS.
- Make sure CAL TSS is supposed to be available at this hour of the day.
- Make sure somebody else isn't using this console.

{Send a PANIC.}

<table>
<thead>
<tr>
<th>no</th>
<th>response</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Are you really sure the console is OK?

<table>
<thead>
<tr>
<th>no</th>
<th>response</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

It looks like your console is down or the system is down.

<table>
<thead>
<tr>
<th>response say something</th>
<th>about no space?</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

Congratulations. You are in the LOGIN procedure. See the examples.

This means that the console was already logged in (perhaps that man hurrying across the room with his cup of coffee will shed some light on the situation). This is your problem. You can PURGE the guy and log him out if that is your style or try to find him if you are more solicitous.
PROCEDURE II - the user is logged in and using the console and has either forgotten what he was doing or gotten into some mysterious state where the console doesn't respond the way he expects it to:

[REMEmER THAT ALL INPUT LINES END WITH A CARRIAGE RETURN]  [THE KEY MARKED RETURN ON TELETYPES]!!!

If you haven't already done so, look up the prompt character in the table. (Subsystems signal that they are ready to process a request by printing a character at the beginning of the line. The table will help you identify the subsystem if there is a prompt character visible.)

no

[If you have just typed something, did the characters echo]  (print)?

yes

[If the lines are being happily swallowed by the console and no prompt characters are appearing, some subsystem is gobbling them up. Are you perhaps in insert mode in the EDITOR or BASIC? You get out of that mode by entering an empty line (no characters, just the RETURN key.) If you were in insert mode and you enter an empty line, a prompt character should appear and you can go from there.]

Type WHO (followed by RETURN, of course).

| no | response |
|    |          |

|        | Civilized subsystems respond to this query by announcing their name. Barbaric subsystems are likely to treat it as a nonsense command and print some irrelevant diagnostic. In either case, the table should tell you what's going on. |

Send a PANIC

| no | response |
I

response

| Some subsystems field (minor) PANICS and allow you to resume control. Others dump the PANIC and the BEAD GHOST appears. You can tell the BEAD GHOST to abort the subsystem by saying PURGE and you will get back to the Command Processor. (You can also poke around in the subsystem with the BEAD GHOST if you are debugging it, but that is fairly sophisticated.) |

| Send a MAJOR PANIC |

| no | response |

| It looks like your your console or the system is down. |

| A subsystem which swallowed PANICS was in execution. No system-provided subsystem should behave this way. Either it was a non-standard subsystem, or CAL TSS has a bug. |
PROCEDURE III - the user has just started something he wishes he hadn't

Send a PANIC

<table>
<thead>
<tr>
<th>no response</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Nice subsystems will stop what they're doing and
wait for the user to tell them to do something
else. Not-so-nice subsystems will duck the PANIC
and the READ GHOST will appear. The user can
abort the subsystem and get back to the
Command Processor by typing PURGE. Or
if he decides that whatever was going on was
OK after all, he can tell the READ GHOST to
make the subsystem continue exactly what it was
doing when interrupted by typing RETRY.

Send a MAJOR PANIC

<table>
<thead>
<tr>
<th>no response</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

It looks like your
your console or the
system is down.

A subsystem which swallowed PANICS
was in execution. No system-provided
subsystem should behave that way. Either
it was a non-standard subsystem,
or CAL TSS has a bug.

1.10 The Line Collector

Unless the user does something extraordinary, all console input goes through a piece of software called the Line Collector, which provides a large number of ways to correct/change the line being entered. The chart below indicates the various manipulations that can be performed; to invoke a given function, hold down the CTRL key and type the relevant key. A detailed explanation is available in the "Users Guide", sec. III.2.3. Here we give two examples and encourage the user to experiment. Underlined characters represent one key or a combination of keys, not the sequence of keys given by the individual underlined characters; blanks that might otherwise be "invisible" are also underlined.

First note that the Line Collector maintains the previously typed line as the old line and uses it, in conjunction with typed characters, to construct a new line. Whenever the new line is accepted (by typing RETURN, for example), it becomes the old line.

Suppose the user is talking to BASIC and has just entered the line (considered as the old line) below (which will have provoked a message from BASIC objecting to the line).

```
old line:  PRNIT X
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
<th>and the teletype responds</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTRL-1</td>
<td>make an insert at the beginning of the old line</td>
<td>&lt;</td>
</tr>
<tr>
<td>10_</td>
<td>this is what is to be inserted</td>
<td>10_ PRNIT X</td>
</tr>
<tr>
<td>CTRL-O</td>
<td>copy the rest of the old line (all of it) into the</td>
<td>and the carriage will return.</td>
</tr>
<tr>
<td></td>
<td>new line and accept the new line.</td>
<td></td>
</tr>
</tbody>
</table>

BASIC will issue another diagnostic as it still will not recognize the line as a valid statement.

```
old line:  10 PRNIT X
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
<th>and the teletype responds</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTRL-D</td>
<td>copy the old line into the new line up to the first occurrence of the next character typed</td>
<td>no response</td>
</tr>
<tr>
<td>N</td>
<td>you wanted IN and made a mistake</td>
<td>10 PR IM</td>
</tr>
<tr>
<td>IM</td>
<td>erase the M</td>
<td>IM</td>
</tr>
<tr>
<td>CTRL-Q</td>
<td>copy the rest of the old line into the new line</td>
<td>T X</td>
</tr>
<tr>
<td>N</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
July 1971

'Y'

RETURN

you remembered to print Y

you are satisfied with your
new line

and the carriage will return

BASIC should accept this line, which is

old line: 10 PRINT X,Y

2. Examples.

These examples are not all-inclusive. They are provided to give a feeling of how CAL TSS works, plus a few pointers on how to do some commonly useful things. The first example is heavily commented, subsequent ones are commented only where they contain points of special interest. Characters typed by the system have been underlined in the first example to distinguish them from the things that the user typed. Subsequent examples are not underlined.

EXAMPLE 2.1 – SIMPLE USE OF BASIC, NC FILES KEPT

1.0 These lines constitute the login procedure. Prior to the first line, the user has attracted the attention of CAL TSS by typing P while holding down the CTRL and SHIFT keys.

1.1 'GUEST' is the name given for the permanent directory.

1.2 The password to use the GUEST directory is also 'GUEST', but the password is not usually the same as the directory name.

1.3 'JOHN' is the name the user chose to give to the temporary directory.

2.0 The appearance of the Command Processor signals the successful completion of the login procedure.

2.1 The user tells the Command Processor that he wants to use the BASIC subsystem.

3.0 All these lines are a conversation with the BASIC subsystem.

3.1 BASIC announces its presence and signals that it is ready to process commands by printing '->'.

3.2 The user gives it an immediate command to print the value of pi and it responds with the value.

3.3 Now the user decides to construct a simple BASIC program, so he begins entering indirect statements. These lines constitute the text of the BASIC program being constructed.

3.4 This is an example of erasing a mistake. The arrow printed because the user typed CTRL-Q to erase the 9. The actual line entered was '20 LET Y = 18'.

3.5 The user forgot a comma in this line, so BASIC does not recognize it as a valid statement and complains. The correct line is entered.

3.6 The user tells BASIC to run the program he just constructed and it runs the program and prints the results.

3.7 He decides to change the program and types the request 'LIST 30', which types line 30 for inspection.

3.8 The user tells BASIC that he is going to edit that line, so it is made the old line in the Line Collector.

3.9 This line was constructed by typing CTRL-H, which copied all of the old line, and then typing ',X/Y' followed by RETURN.

3.10 The user now runs his program again and the new results appear.

3.11 The PIN command tells BASIC that the user is finished. BASIC warns the user that changes have been made in the program which will be lost if the user does not use the SAVE command to save the new program. The user repeats PIN to inform BASIC that he does not wish to save the program he has constructed.

4.0 The Command Processor resumes control of the console.

4.1 The user signals that he is finished using the system by typing 'LOGOUT'. The system prints the accounting data for the run and after it wishes him a good day, the console goes dead.
This page no longer contains information.

EXAMPLE 2.2 - CREATION OF PERMANENT DISK FILES TO BE KEPT FOR FUTURE SESSIONS

1.0 This is the login procedure again, except that the permanent directory name is 'USER:V' and the password is 'QRBL'. 'V' has been chosen as the name for the temporary directory.

2.0 The user tells the Command Processor to call the subsystem SERVICES.

3.0 These lines are a conversation with SERVICES.

3.1 The user requests SERVICES to make a new disk file by saying NEWDF. He has asked that it be created in his permanent directory and named AUTO.

3.2 The command 'PCAP OWN.KEY' causes the user's private access key to be displayed. This is done so that he can see the number of the access key, which is required by the command which adds locks to names. The number is the 53002 which occurs in the second line.

3.3 This command adds lock 53002 matching his OWN.KEY, to the file AUTO in his PERMDIR. The string of 7's are the kinds of access which the user is allowing, namely all kinds of access. The addition of this lock to the name 'AUTO' makes the file AUTO available in the BEAD name space, and it will automatically be available whenever he logs on in the future.

3.4 A mistake was made in entering this line; the first 'I' was erased by typing CTRL-Q. The line actually entered was 'NEWDF PERMDIR:MANUAL', which creates a new file MANUAL in the user's PERMDIR.

3.5 Because the user decided not to have automatic access to MANUAL, he set up a name in TEMPDIR which can be used to access MANUAL during this console session. The sense of this command is to allow the file MANUAL in PERMDIR to be referred to as M in TEMPDIR.

3.6 This dismisses SERVICES and the Command Processor returns.

4.0 The Editor is used to put some text in the files AUTO and MANUAL, alias M, for future sessions.

EXAMPLE 2.3.1 – USE OF A PREVIOUSLY CONSTRUCTED FILE IN BASIC

1.0 Only the interaction with BASIC is described, although the reader should note that no special manipulations were done after login to get access to AUTO.

1.1 The command 'LOAD AUTO' tells BASIC to load the file AUTO.

1.2 The user may not have noticed the mistake made when constructing AUTO, but BASIC does notice. It prints a diagnostic message followed by the offending statement.

1.3 After BASIC has read the whole file, it prompts again. The user tells it to list the program.

1.4 The program is printed and he sees that the statement in error has been left out.

1.5 This is the correct form of the statement.

1.6 He asks that the program be run and the results are printed out.

1.7 Because the user made a correction to his program, he wants to save the new version, so he does a 'SAVE'. The FIN leaves BASIC destroying the program in it.

EXAMPLE 2.3.2.2 - ACCESS FOR SUBSYSTEMS TO ALL YOUR PERMANENT FILES

1.0 This conversation with SERVICES makes the user's PERMDIR look like part of his TEMPDIR and hence gives access to his permanent files to all subsystems which have access to the temporary files.

1.1 CHAIN causes the first directory, PERMDIR, to have the second directory, TEMPDIR, appended to it. Oops, that's backwards.

1.2 So UNCHAIN takes any appended directory out of PERMDIR.

1.3 Now CHAIN appends PERMDIR to TEMPDIR, which is what the user was trying to do. If he hadn't unchained PERMDIR from TEMPDIR back at step 1.2, the two directories would constitute a loop and the code which looks up names would get annoyed if it ever used them.

2.0 The same use of BASIC as in the previous example.

EXAMPLE 2.4 - SCOPE SIMULATOR: A SIMPLE INTERACTIVE FORTRAN PROGRAM

This example was generated when the system was fairly busy. When the user tried to log on, he was refused access because there was no space to accommodate him. The space fluctuates on a short time scale, so the user just kept trying until he got on. Subsequently, the SCOPE subsystem requested additional space which was not immediately available and CAL TSS printed the messages saying 'waiting at top of queue...' and 'waiting for access to...' so that the user would be forewarned that processing his request might take longer than usual.

1.1 The reader has seen this before. The file TRIVIA in PERMDIR is made available in TEMPDIR as INPUT.
2.0 The file is printed with the Editor.
2.1 Notice the special file names used to talk to the console.
3.0 The user asks for the SCOPE Simulator. Characters typed by the user are underlined in this section.
3.1 SCOPE requests the SCOPE Simulator and the 40000 is an optional parameter which determines the initial FL in the Simulator. If it is omitted, a default value of 14000 is used. 40000 is required to use the RUN compiler so that is why this value was chosen. SCOPE prints the time and date.
3.2 > is SCOPE's prompt character, signalling that it is ready to process a request. The user may type the same commands that he would have put on his control cards when using the batch system. In particular, RUN causes the FORTRAN compiler to compile statements from the file INPUT.
3.3 Another command causes the compiled program to be loaded and executed.
3.4 The previous line was printed by the user's program. The | is the prompt character which signals that a program running on the simulator is waiting for input, as opposed to the simulator itself. After the user responds 'GEORGE', (followed by RETURN, of course), the program grinds to its rather uninspiring conclusion and SCOPE starts watching the console again.
3.5 SCOPE prompts for another command and the user dismisses it. The Command Processor reappears.

WOULDP ANYONE OUT THERE LIKE TO HEAR SOME POEMS?
"SURE

HELLO. WHAT IS YOUR NAME?
"VANCE

I WRITE POETRY. WOULD YOU CARE FOR A POEM, VANCE?
"YES

GOOD. I SPECIALIZE IN WRITING HAIKU. SHALL I EXPLAIN
ABOUT THE FORM IN WHICH HAIKU ARE WRITTEN?
"NO THANX

VANCE, I ALWAYS FIND ONE'S PHONE NUMBER A KEY TO
PERSONALITY. WHAT IS YOUR PHONE NUMBER?
"6425823

NAME A SEASON--OR IF YOU PREFER I'LL CHOOSE ONE
"SUMMER

THANK YOU. SUCH A LOVELY SEASON. IT INSPIRES ME.
July 1971

FISHERMAN'S BOAT DRIFTS
GLIMPSE OF YELLOW PINE POLLEN
FIREFLIES WANDERING.

WOULD YOU CARE FOR ANOTHER POEM?

NO

I UNDERSTAND, VANCE. THE SOUL CAN TAKE ONLY
SO MUCH POETRY AT ONE TIME.

WOULD ANYONE OUT THERE LIKE TO HEAR SOME POEMS?

NO

THAT'S ALL RIGHT. I'M WRITING A SONNET CYCLE

EXAMPLE 2.5 - SCOPE SIMULATOR: AN INTERACTIVE SNOBOL PROGRAM USING A FILE FROM A FRIEND'S DIRECTORY directory

This rather complicated example involves four separate console sessions.

1.0 The whole purpose of this session is to find out the number of the user's access key so that his friend can add it to the files she wants to let the user use.

1.1 The user tells SERVICES to print OWN.KEY so that he can see its number, which is 123401.

2.0 This session is done by the user's friend, in order to add locks matching the user's key to her files.

2.1 These commands to SERVICES add locks matching his key, which is 123401, to his friend's files REACT and DATA in her permanent directory. Only read access is allowed by the option lists 71420.

3.0 Now the user is going to make links in his own permanent directory to his friend's files.

3.1 This is an example of typing first and thinking later. None of these commands did anything except provoke nasty messages from SERVICES.

3.2 Finally, FRIENDP causes a search to be made for a permanent directory named 'USER:VV', and if one is found, a link to it named 'VV' will be placed in TEMPDIR. If a permanent directory USER:VV isn't found, the user will get some message like the ones printed above.

3.3 These commands make links in PERMDIR named 'REACT' and 'DATA' to files REACT and DATA in the directory VV. The meaning of 'VV:REACT;OWN.KEY' scans roughly as: find something named 'VV', (which will be the permanent directory of the user's friend USER:VV) and look up file REACT in that directory using the access key OWN.KEY.

3.4 These commands have been seen before. They give automatic access in the future to the files named by 'REACT' and 'DATA' in the user's permanent directory. Even though the locks added here would allow all kinds of access, read only access is all that is allowed because of the locks on REACT and DATA in USER:VV.

4.0 This session uses the files to which the user has laboriously gained access. It is program written in SNOBOL which interacts with the console and writes poetry.

4.1 The user calls SCOPE and invokes SNOBOL on his file REACT.

4.2 Most of the rest of this example is a conversation with the poet. Lines which start with the ' indicate that the poet is waiting for the user to say something and the characters after the ' are whatever the user chooses to respond.

4.3 When interest in poetry wanes, the poet goes away and SCOPE resumes watching the console. The user leaves much edified.

EXAMPLE 2.6 - LOGIN PROBLEMS ILLUSTRATED

1.0 When the user sent his CTRL-SHIFT-P to CAL TSS, there wasn't enough space to accommodate him. The space in the system fluctuates on a fairly short time scale, so trying again every few seconds will generally get the user on before he can get annoyed.

2.0 This interaction illustrates the consequences of most of the mishaps that can occur during login.

2.1 'UNEXPECTED PRETURN' means that there is not a permanent directory named 'VV'.

2.2 'BAD SYNTAX' indicates that 'USER:VV;' is not even a possible name for a permanent directory.

2.3 Self-explanatory.

2.4 'DUPLICATE TEMPDIR' means that someone else has already named his TEMPDIR 'PAUL'. The user must keep choosing a new name until he gets one that does not conflict.
3.1 Summary of the Editor

The Editor subsystem enables the TSS user to construct and edit files of coded information. A file consists of lines, where a line is a string of coded characters ending with a carriage return character (generated by the RETURN key on the teletype).

The Editor is called by typing a command of the form:

```
EDIT filename filename
```

where `filename` is the name of the file to be edited and `filename` is the name of the file that the results are written on. `filename` is the default value of `filename`. All file names are specified by standard parameters. The Editor prompts by typing `:` and awaits a request. At any given time the Editor is looking at a specific line called the current line. When the Editor is first called, the current line is a pseudo-line which is always the top line of every Editor file.

The following requests may be typed to move about the file for the purpose of creating, deleting, or editing text lines. Each request is terminated either by a carriage return or, if more than one request is made on one line, by a semi-colon. Some requests contain a "stop condition" or line specifier, represented by `sc` below. Such requests affect all lines from the current line to the line specified by `sc`, inclusive. (If you've lost track of the current line, request 'P' and the Editor will print it.) `sc` may be:

1) a decimal number, specifying the line that number of lines from the current line,
2) 'str' (where `str` is any string of characters except semi-colon), specifying the next line containing the string of characters,
3) '/str', specifying the next line starting with the given string of characters, ignoring leading blanks,
4) '$', specifying the bottom, or end, of the file,
5) omitted, specifying the current line.

After the Editor has processed the request, the line specified by the request becomes the new current line.

<table>
<thead>
<tr>
<th>Requests</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Insert, after the current line, the lines which follow. Insertion is ended by entering a null line (carriage return only).</td>
</tr>
<tr>

<td>Move to the top of the file (pseudo-line).</td>
</tr>
<tr>
<td>Msc</td>
<td>Move forward over the specified lines.</td>
</tr>
<tr>
<td>Bsc</td>
<td>Move backward the specified number of lines.</td>
</tr>
<tr>
<td>Psc</td>
<td>(NOTE: <code>sc</code> can only be a number.) Print the specified lines.</td>
</tr>
</tbody>
</table>
November 1971

C/str1/str2/sc  Replace the first occurrence of str1 by str2 in the specified lines.
C6/str1/str2/sc  Replace every occurrence of str1 by str2 in each of the specified lines.
Esc            Edit the specified lines using the Line Collector. *

R,filename                   Insert the contents of file filename after the current line.
W,filename,sc            Write the specified lines, including the current line, into the file filename.

P,filename                   Finished - create the file filename from the latest version; simply entering "P" causes the updated text to replace the original file filename specified when the Editor was called. Finished but do not save any file.
Q

The Editor prompts with: and responds ??? to lines it does not understand.

* Each line being edited is made the old line in the line collection and may then be altered using the Line Collector. (See section 1.10 on the Line Collector.)
5 If filename is null a CP name is requested on the next line.
3.1 Summary of the Editor

The Editor subsystem enables the TSS user to construct and edit files of coded information. A file consists of lines, where a line is a string of coded characters ending with a carriage return character (generated by the RETURN key on the teletype).

The Editor is called by typing a command of the form:

```
EDITOR fname
```

where `fname` is the name of the file to be created and/or edited. All file names are looked up in the BEAD name space. The Editor prompts by typing `: ` and awaits a request. At any given time the Editor is looking at a specific line called the current line. When the Editor is first called, the current line is a pseudo-line which is always the top line of every Editor file.

The following requests may be typed to move about the file for the purpose of creating, deleting, or editing text lines. Each request is terminated either by a carriage return or, if more than one request is made on one line, by a semi-colon. Some requests contain a "stop condition" or line specifier, represented by `sc` below. Such requests affect all lines from the current line to the line specified by `sc`, inclusive. (If you've lost track of the current line, request `P` and the Editor will print it.) `sc` may be:

1) a decimal number, specifying the line that number of lines from the current line,
2) `'str` (where `str` is any string of characters except semi-colon), specifying the next line containing the string of characters,
3) `'/str'`, specifying the next line starting with the given string of characters, ignoring leading blanks,
4) `'$'`, specifying the bottom, or end, of the file, or
5) omitted, specifying the current line.

After the Editor has processed the request, the line specified by the request becomes the new current line.

<table>
<thead>
<tr>
<th>Requests</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Insert, after the current line, the lines which follow. Insertion is ended by entering a null line (carriage return only).</td>

<td>Insert the contents of the file <code>frame</code> after the current line.</td>
</tr>
<tr>
<td>W,<code>frame</code>,sc</td>
<td>Write the specified lines, including the current line, into the file <code>frame</code>.</td>
</tr>
<tr>
<td>F,<code>frame</code></td>
<td>Finished - create the file <code>frame</code> from the latest version; simply entering 'F' causes the updated text to replace the original file specified when the Editor was called. Finished but do not save any file.</td>
</tr>
<tr>
<td>Q</td>
<td></td>
</tr>
</tbody>
</table>

The Editor prompts with `:` and response `????` to lines it does not understand.

* Each line being edited is made the old line in the line collection and may then be altered using the Line Collector. (See section 1.18 on the Line Collector.)
3.2 Summary of BASIC

BASIC is an easy-to-learn, general-purpose programming language similar to FORTRAN but created specifically for time-shared computing environments. For details see the description in the CAL Computer Center Users' Guide, available at the Computer Center Library.

BASIC accepts two types of statements: 1) indirect, which are saved to be executed sequentially as a program at some other time; 2) direct, which are carried out (executed) as soon as they have been entered using the carriage return key (direct statements, especially the PRINT statement, allow the teletype to be used as a very powerful desk calculator).

Although some statements may be used only directly (or indirectly), most statements may be used either way. All indirect statements must begin with a line number and are executed in order of ascending line numbers. Those without line numbers are assumed to be direct. Statements which may be indirect only are those that would only make sense in a program. Statements which may only be direct are usually for changing the program itself rather than the data it works on.

BASIC is called by typing a command of the form:

```
BASIC filename
```

where `filename`, if specified, is a file containing a BASIC program to be loaded. BASIC responds with BASIC VERSION ... after which either direct statements or a program of indirect statements may be entered.

BASIC prompts with -.

There are three ways to enter a program of indirect statements:

1. Pass BASIC a file `filename` as the first parameter when it is called; the file is loaded in the same manner as when a 'LOAD' command is given.

2. Use the 'LCAD' command to read in a program from a file. Lines containing errors will be typed out after an error message and are not included in the program.

3. Create a new program by typing it into BASIC. Lines with errors will not be saved.

Sample BASIC program starting from the Command Processor:

```
BASIC
100 PRINT "NUMBER", "SQUARED", "CUBED"
105 PRINT
110 FOR X=1 TO 10
120 LET S=X*X
```
July 1971

130 PRINT X,S,X*S
140 NEXT X
150 END

RUN

<table>
<thead>
<tr>
<th>NUMBER</th>
<th>SQUARED</th>
<th>CUBED</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>9</td>
<td>27</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>64</td>
</tr>
<tr>
<td>5</td>
<td>25</td>
<td>125</td>
</tr>
<tr>
<td>6</td>
<td>36</td>
<td>216</td>
</tr>
<tr>
<td>7</td>
<td>49</td>
<td>343</td>
</tr>
<tr>
<td>8</td>
<td>64</td>
<td>512</td>
</tr>
<tr>
<td>9</td>
<td>81</td>
<td>729</td>
</tr>
<tr>
<td>10</td>
<td>100</td>
<td>1000</td>
</tr>
</tbody>
</table>

EXECUTION COMPLETE

Now the user may:
1. Edit his program using direct statements and rerun it.
2. Quit (and return to the Command Processor) by typing FIN.
3. Save his program by typing SAVE frame.

List of Indirect or Direct Statements

LET var=[...var=]expr
Each variable takes on the value of the expression.
Example: 10 LET A=B=4.35-F

DIM array(dim list)[,...,array(dim list)]
Reserve space for arrays with more than two dimensions and/or dimensions > 10.
20 DIM A(60),L(5,N,3*N)

SIG expr
Number of significant digits printed for numbers is changed to the value of expr.
Example: 30 SIG N

DEF FN letter(param)=expr
Defines a one line function whose name has three letters starting with FN and whose single dummy parameter is param.
Example: 35 DEF PNG(X3)=X3/10 - A0/X3

READ var[...var]
Reads from a DATA defined list and assigns values to the variables

A variable may only be a letter optionally followed by a digit, or by a list of expressions separated by commas and enclosed in parentheses.
in sequential order.
Example: 40 READ A,B,G2

INPUT var[... var]
Requests input values from the TTY by typing ? and assigns values to the variables in sequential order.
Example: 12 INPUT A,B,C

PRINT [... ITEM]
Prints and/or moves the teletype head as indicated by the item(s) which may be num expr, string var, 'characters', TAB(expr), .. ; and :.
Example: 100 PRINT "VALUE ", TAN(B1*B1)

RESTORE
Restores the pointer into the DATA bank to the top.

IF log expr GOTO lnum
IF log expr THEN lnum
Transfers control to the statement with line number lnum if the logical expression is true.
Example: 105 IF A>B/SIN(X) GOTO 115

GOTO lnum
Transfers control to line number lnum.
Example: 20 GOTO 300

ON expr GOTO lnum[... lnum]
If expr has value=1, GOTO statement having first lnum in list; if expr has value 2, GOTO statement having second lnum in list, etc.
Example: 10 LET X=1
20 ON X GOTO 30,40,50
transfers to statement 30.

REM char string
A comment statement.

GOSUB lnum
Go to the statement specified by the line number but return to the line following the GOSUB when a RETURN statement is encountered.

MAT READ c - Reads values from DATA list into array c.

MAT PRINT c - Prints values from array c.

MAT c = TRN(a) - Matrix c becomes transpose of a.

MAT c = ZER - Zeros every element in matrix c.
MAT c = IDN - Square matrix c is set to identity matrix.
MAT c = CCN - Array c is set to all ones.
MAT c = a+b - Array c is set to the sum of a plus b.
MAT c = a-b - Array c is set to the difference between a and b.
MAT c = a*b - Array c is set to the product of a and b.
MAT c = (expr)*b
Array c is set to the scalar product of expr and b.
MAT c = INV(a) - Matrix c becomes the inverse of a.

List of Indirect Statements

DATA val[...val]
Forms a list of data values to be used by READ statements.
Example: 12 DATA 5,7,3,30+52

PAUSE[str]
Execution pauses and str, if given, is printed. BASIC will accept
direct statements or editing request; execution resumes if CONTINUE is entered.

END
Ends execution; must have highest line number.

STOP
Stops execution (acts like a jump to END statement).

FOR var=expr TO expr[STEP expr]
NEXT var
Defines the limits of a loop. The three expressions give the
initial values of the control variable, the terminating value and
the increments, if not equal to 1.
Example: 40 FOR I=1 TO 10 STEP .5
50 LET S=S+I
60 NEXT I

RETURN
Execution goes to the line following the last GOSUB for which no
RETURN has been executed.

List of Direct Statements

LIMIT integer
Specifies a maximum number of statements that can be executed
without control returning to the console; prevents infinite loops.
RUN
Causes execution of the program beginning with lowest line number.

CONTINUE
Execution continues where it last stopped.

LIST [line_number[-line_number]]
Prints out the specified lines on the teletype. If the line numbers are omitted or are replaced by 'ALL', then the entire program is printed.

DELETE line_number[-line_number]
Deletes the specified lines from the program. If 'ALL' is typed instead of the line numbers, then the whole program is deleted. Note that this statement has no effect on the values that may have been stored into any variables.

EDIT line_number[-line_number]
The specified lines are passed one at a time to the line collector for editing. Note that if the line number is altered so that it is larger than what it was before but is still smaller than the number of the last line in the range specified, then the line will be edited again when the new line number's turn comes.

LOAD [fname]
Loads a program from a text file of the given name. (No lines which may have been entered into BASIC are deleted.) The name, if given, is a simple name which is looked up using the scan list SCANI, created by the system in the user's temporary directory. SCANL looks for the file in the user's temporary directory, his permanent directory (with the user's own access key) and then in the public directory. To type a more complicated name, fname is omitted and a prompt character quote ("), will appear, after which any Command Processor name can be specified.

SAVE [fname]
Writes all the text onto a file of the given name, which must be in the same format as for load. However, if a name is given and no file by that name exists, then a new file is created in the user's temporary directory with that name.

WHO
Types out BASIC.

QUIT
FIN
Both of these statements return to the Command Processor after destroying any program that may have existed.
July 1971

### 3.3 Summary of the SCOPE Simulator

SCOPE provides an operating environment for many programs written for CAL's 6400 batch system (SCOPE 3.0 or CALIDOSCOPE), as well as real-time control over the construction and execution of such programs by a user at a console.

**SCOPE is called with the following command:**

\[
\text{SCOPE } \text{fl}
\]

where \( \text{fl} \) is an optional parameter specifying the field length. When omitted, 14000 is the default value. SCOPE responds by typing the date and time and then awaits requests after typing \( > \), which is its prompt character. Programs executing under SCOPE prompt with \( > \) when they want input from the console.

SCOPE creates several standard files necessary for its operation whenever it is called, notably a SYSTEXT file called 'OUTPUT'. Whenever it needs a file to process a request, it gets it from the BEAD NAME SPACE. If there is no file by the appropriate name available, one is created in TEMPDIR.

### SCOPE Simulator Requests

<table>
<thead>
<tr>
<th>Request</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT, fname</td>
<td>Declare a new SYSTEXT file <code>fname</code> (will not change to SYSTEXT a file which already exists in another mode).</td>
</tr>
<tr>
<td>FILE, fname</td>
<td>Use the file <code>fname</code> as the source of SCOPE Simulator requests.</td>
</tr>
<tr>
<td>MSG, OFF or ON</td>
<td>Suppresses program messages to the console or restarts them.</td>
</tr>
<tr>
<td>GET, fname</td>
<td>Get the file <code>fname</code> from the BEAD NAME SPACE.</td>
</tr>
<tr>
<td>PUT, fname</td>
<td>Return <code>fname</code> to its directory.</td>
</tr>
<tr>
<td>STEP</td>
<td>Trace calls made on the Simulator by code setting cell 1.</td>
</tr>
<tr>
<td></td>
<td>SCOPE will print each cell 1 call in octal and then await a response:</td>
</tr>
<tr>
<td></td>
<td>B  call the debugger</td>
</tr>
<tr>
<td></td>
<td>S  perform the request</td>
</tr>
<tr>
<td></td>
<td>E  ignore the request and perform END instead</td>
</tr>
<tr>
<td></td>
<td>G  leave step mode and then perform the request</td>
</tr>
<tr>
<td>FIN</td>
<td>Exit from SCOPE Simulator.</td>
</tr>
</tbody>
</table>

### Loading Requests:

<table>

**All RUN FORTAN Library Routines**
3.4 SERVICES and the BEAD GHOST

This section consists of a list of the commands understood by SERVICES and the BEAD GHOST. An attempt has been made to indicate what sort of parameter(s) each command expects, and some examples of the different kinds of parameters are given below. A few of the commands are understood by only one or the other of the dynamic duo, and they are so marked. The commands are written in caps, the parameters are underlined. The command and the parameters are separated by one or more blanks.

FIN  is the command which terminates SERVICES; it is not understood by the BEAD GHOST
PURGE  (BEAD GHOST only) aborts the current subsystem and returns to the Command Processor
RETRY  (BEAD GHOST only) resumes execution of the current subsystem right where it quit
RETURN  (BEAD GHOST only) resumes execution of the current subsystem without re-executing the most recent system call, if that call provoked an error

NEWPSW password  changes the user's password to password
NEWDF direct:fname  creates a file fname in the directory direct
ADDKEY keynum obits dirloc  adds a lock which can be opened by the access key keynum to directory entry dirloc; the kinds of access allowed to wielder of keynum are defined by obits
DELKEY keynum dirloc  revokes privileges of access to the directory entry dirloc for holders of access key keynum
FRIENDP direct obiloc  if there is a permanent directory named direct, access to it is placed in obiloc; the access is highly restricted
FRIENDT direct obiloc  same as FRIENDP, except temporary directories
PCAP object  prints the indicated object
PDATA datum  prints the indicated datum
PDATA datumloc datum  prints datum words of data, starting at datumloc
MCAP object obiloc  places a link to object at obiloc
MDATA datum datumloc  moves datum to datumloc
CHAIN direct1 direct2  makes direct2 look like an extension of direct1
UNCHAIN direct  eliminates any extension of direct
NEWV ident  creates a new variable ident
KILLY ident  eliminates the variable ident
DLIST direct  prints the contents of the directory direct
SPACE datum1 datum2 datum3 datum4  resources are reserved for the user; see section on space control
MSPACE direct1 datum direct2  datum sectors of disk space are moved from
direct1 to direct2. One must be the father of the other. (One sector=64 words)
creates new user subordinate to the user (i.e., a new permanent directory named ident of size datum as a son of the user's permanent directory)
the permanent directory ident is eliminated from the user's permanent directory and destroyed
creates a directory ident on the user's permanent directory of size datum
creates a new file block at filadr
deletes the file block at filadr
creates a new access key at objloc
deletes the indicated object
removes the link at dirloc
the ownership entry at dirloc is removed and the owned object is destroyed
sets the print mode to print 20 successive octal digits
sets the print mode to print 60 bit words in groups of 4,7,7,7,7,7,7,7,7, useful for decoding text files which the user has somehow been reduced to inspecting in octal
sets the print mode to print octal digits in groups of 15, useful for dumping code files (this is the default mode)
the mode of numbers typed into the Command Processor complex is to be octal if not expressly marked otherwise (this is the default mode)
the mode of numbers typed into the Command Processor complex is to be decimal if not expressly marked otherwise.
COMMAND PROCESSOR
SERV SERVICES WHO

SYSDOWN DECIMAL?
Parameters

datum parameters are evaluated to 60-bit integers; notice that if the user gives the name of a datum, the datum is looked up for him.
Examples:

7 represents 7
11 represents 9, if 'IN.OCT'
11 represents 11, if 'IN.DEC'
5+10-15D represents -2, if 'IN.OCT'
VARIABLE+4 represents 7, if VARIABLE contains 3
7CB+(#52B+4) represents 56 plus the contents of cell 46 in the subsystem which just call the BEAD GHOST

datumlloc parameters specify places where data can be kept.
NAME A variable called 'NAME'
FILE#O The first word of a file FILE in the Command Processor name space
#10 Cell 8 of the subprocess calling the BEAD GHOST

direct parameters specify a directory
PERMDIR The user's permanent directory
TEMPDIR The user's temporary directory
USER:VV The directory name 'VV' in the USER directory
USER:VV:P The directory named 'P' in the directory named 'VV' in the etc.

dirloc parameters specify names of files in directories
TEMPDIR:INPUT A file in the user's TEMPDIR
TEMPDIR:VV:REACT A file in the directory named VV in the user's TEMPDIR

filadr parameters specify addresses within files
INPUT#O Word 0 of a file INPUT named in the Command Processor name space
TEMPDIR:VV:REACT#100 Word 64 of the file mentioned above

fname is any legal file name; here are mentioned only strings of alphanumeric characters

INPUT
MYFILE10

ident is again, any string of alphanumeric characters, blanks excluded
keynumb is just a datum with a different name

301 Access key number 301
VARIABLE Same, if VARIABLE=301

object is a two-word set of information which is the internal form of stuff kept by the system, like files and directories and access keys; if the user specifies an object, the object will be fetched.

OWN.KEY The user's private access key
SCANL The user's private name space

object parameters specify places where objects are kept, such as directories and variables

VARNAME The user can create a variable VARNAME and move objects to it
PERMDIR:FILENAME A dirloc is a special form of object
PROPOSED CHARGES FOR TSS 10/8/71

I) A basic machine rate of $200 per hour, divided up as proposed in "A note on charging" of 8/17/71. This results in the following rates: (rounded to 2 figures.)

- CPU: $130.00 per hour
- ECS: $ .29 per 10^3 words-hour
- Temporary disk: $ .047 per 10^3 sector-hour

II) A connect charge rate so set that the effective connect charge for no activity is

- Direct wired TTY: $2.00 per hour
- Dial up lines: $2.50 per hour

III) Permanent disk space charged at the effective rate of temporary disk space for 200 hours per month. This rate will not depend on the number of hours the system is actually in service.

- Permanent disk space: $9.40 per 10^3 sector-month

A NOTE ON CHARGING

INTRODUCTION

Within the next few weeks it will be possible to begin charging for the use of TSS. In fact we will probably begin testing the charging procedures on live customers within a week. This note will explore various rationales for setting rates and the resulting charges for a few standard tasks.

RATIONALES

There are a number of different ways to set rates. The method used in this note is to set a nominal rate for the machine as a whole. This rate is then partitioned among the various resources for which we can account. The actual rate for the machine as a whole will then depend on the percentage of utilization of each of these accountable resources. The nominal rate for the machine as a whole is then adjusted on an ad hoc basis to obtain the desired income.

Another method, not used in this note, is to attempt to set the rate for each piece of equipment so as to pay its costs. Thus, for example, if disk storage becomes full there would be enough income from the disk itself to pay for another. This method has a number of problems. Not all components can be extended at will and all components are not accounted. Moreover, this method makes no allowance for various overhead costs, such as system programmers. It might be worthwhile to examine this method later.

Once a nominal overall rate has been set, it must be partitioned among the accountable components. The obvious method that presents itself is to divide the rate proportional to the cost of each component. This leads to similar problems to the other method, i.e., not all components can be accounted, and not all of each accounted component can be accounted. Another problem is that one of the accountable items, connect time, is not a component.

We can charge for part of each of the major components: CPU, ECS and the disk. One procedure is to just ignore all other components, and that is what is done in this note. Another question is whether to weight each component by its full cost and require the accountable portion to pay for the full weight, or to weight each component by the cost of its accountable portion. This is a real problem for ECS since we can only account for half of it. Finally, there is the question of how to determine the cost for a component, by the original cost to the Computer Center, or by a probable replacement cost. These last two questions lead to four possibilities, and in later computations all of them are examined.
**STANDARD TASKS**

There are a number of standard tasks considered in this note. The first is the null task. The cost for just logging in to the system and doing nothing, the so-called connect charge. This must be distinguished from a charge for connect time alone, since while a TTY is logged in it is sitting on some resources that are accounted. The total connect charge would be the sum of the charge for connect time alone and the charge for the resources reserved to the TTY.

It will turn out later, under the charging assumptions made in this note, that the charge for the resources reserved to a logged in TTY are quite high, due to a number of inefficiencies in the current system. It is hoped that they will be reduced in the next six months. In the meantime we propose a negative charge for connect time, so as to reduce the total connect charge to a reasonable amount. This amounts to simply permitting the free use of a minimum amount of ECS, and then charging for any additional.

The total resources used by a logged in TTY are 7.5K (decimal) ECS and some disk space. The ECS space comes from two types of overhead. The first is system overhead of 4K of fixed ECS space, which should reduce over the next six months. The second is due to a crude algorithm for the control of swapped ECS space, which also should reduce to near zero under the forced swapped procedures to be installed late this year. The cost of the disk space is ignored, since it is at most $.10.

The next tasks considered will involve the use of the SCOPE Simulator. All estimates of charging assume that ECS will be used for the same length of time as is the CPU. This would be approximately true if only one user is on the system. Since ECS costs will be low compared with CPU costs, the errors can be ignored under low load. Under high load the increase in cost for ECS will become significant, which may lead users to avoid the system during high load.

All of these SCOPE tasks will assume a field length of 45K (octal), sufficient for large assemblies. Under these conditions, the SCOPE Simulator requires 100K (octal) of swapped ECS. In order to run large assemblies more disk space than the nominal amount for a logged in TTY must be reserved. Compared to the cost for CPU this will be small, on the order of $10.00 an hour, and therefore will be neglected.
The particular SCOPE tasks will be: null, null assembly, and large assembly. Under the current system the null use of the SCOPE Simulator, call and return, takes about 12 seconds. Running a null NOMPASS assembly raises the total to about 20 seconds.

The large assembly is one of the decks used in the system itself. The cost on the A machine for assembling the deck under NOMPASS is 1 minute of CPU time and 80 seconds of PPU time. At $400 per hour on the A machine the charge would be about $6.70. Under the current TSS system the cost seems to be about 3 minutes, including the overhead for calling the SCOPE Simulator.

The final task to be considered is that of permanent file storage. We will attempt to compute the costs on a per month basis. Since the system accumulates charges for disk space only while the system is actually running, we need an estimate of the number of hours the system will be up in a month. Since a month has about 700 hours, it is unlikely that the system will be up more than 350 hours.

Next we need estimates of the amount of permanent disk space needed. These are given for three classes of users: small, medium and large. The small user is a student with a very small program to save, say about 1 or 2 pages. We estimate that about 800 words or 12 sectors will be sufficient. The medium user has maybe a 50 page program, about 20 thousand words or 300 sectors. Finally, the large user has maybe 120 thousand words, or about 1800 sectors. (The system cannot support many large users.)

**Rate Setting**

In order to set a rate by the method chosen, we need a nominal rate for the whole machine. For this purpose we have chosen $400 per hour so as to compare with the A machine, which is slightly more than $400 an hour. The B machine is probably somewhat cheaper than the A machine since it does not have as much central memory, nor as many printers or tape drives. The operator overhead for running TSS is considerably less than the SCOPE system, at present requiring an operator only at start up and shutdown, plus an occasional tape mount. The programming staff for TSS is also somewhat smaller than for the A machine.

The TSS should give a much higher rate of utilization for the accounted components than does the SCOPE system, thus inherently producing a higher rate of income for a fully loaded system. ($400 per hour, 24 hours per day, 365 days per year amounts to $3.5*10^6.)
In view of the results that follow, we suggest starting with a basic rate of less than $400 per hour if the desire is to produce a competitively priced system.

Having chosen a basic rate, we need the comparative costs of the various components in order to divide up the rate. The following table contains the basic information used in the subsequent calculations. These values were obtained from Ken Hebert on August 12, 1971.

<table>
<thead>
<tr>
<th>component</th>
<th>original cost</th>
<th>probable replacement cost</th>
<th>standard unit</th>
<th>total standard units (NSU)</th>
<th>accountable units (NASU)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU + 32K CM</td>
<td>.69*10^6</td>
<td>.5*10^6</td>
<td>1 hour</td>
<td>1</td>
<td>.9</td>
</tr>
<tr>
<td>300K ECS</td>
<td>.48*10^6</td>
<td>.6*10^6</td>
<td>1 K-words-hr</td>
<td>300</td>
<td>160</td>
</tr>
<tr>
<td>1/2 disk</td>
<td>.26*10^6</td>
<td>.10*10^6</td>
<td>1 K-sector-hr</td>
<td>1020</td>

</tr>
<tr>
<td>other</td>
<td>.08*10^6</td>
<td>.10*10^6</td>
<td>--</td>
<td>--</td>
<td>--</td>
</tr>
</tbody>
</table>

The following tables contain the computation of the rates per standard unit under different assumptions. The following symbols are used:

- \( R \) = total rate to be distributed (using $400 per hour)
- \( cc \) = component cost
- \( tc \) = total cost for all components
- \( nsu \) = number of standard units in the component
- \( nasu \) = number of accountable standard units in the component
- \( ac \) = cost of accountable portion of a component = \( cc \times nasu/nsu \)
- \( tac \) = total cost of accountable portions of components

Next we give the formulas for the two methods:

**Method A**

\[
\text{rate/s.u.} = R \times \left( \frac{cc}{tc} \right) \times \left( \frac{1}{nasu} \right)
\]

**Method B**

\[
\text{rate/s.u.} = R \times \left( \frac{ac}{tac} \right) \times \left( \frac{1}{nasu} \right)
\]
Method A

<tr>
<td>Disk storage/month</td>
<td></td>
<td></td>
</tr>
<tr>
<td>small (800 wds)</td>
<td>.37</td>
<td>.40</td>
</tr>
<tr>
<td>medium (20K wds)</td>
<td>9.40</td>
<td>9.90</td>
</tr>
<tr>
<td>large (120K wds)</td>
<td>56.00</td>
<td>59.00</td>
</tr>
<tr>
<td></td>
<td>26.00</td>
<td>30.00</td>
</tr>
</tbody>
</table>
FINAL

After consideration of the above results, we propose that:

1) the basic charge rate be $300 per hour.
2) Method B, based on original costs, be used to calculate the rates.
3) a negative connect charge be used so that the basic charge for connect time is about 1 or 2 dollars an hour.

These proposals result in the following rates:

| CPU       | $200.00 per hour |
| ECS      | 0.43 per K-hour |
| disk     | 0.07 per K-sector-hour |

and the following charges for the tasks considered above:

| connect time per hour | $3.01 (not including negative connect fee) |
| SCOPE Simulator per hour | 210.00 |
| null call               | .70   |
| null NOMPASS assembly   | 1.17   |
| large NOMPASS assembly  | 10.50  |

INTRODUCTION TO CAL TSS

Preface

1. General concepts

1.1 Access to CAL TSS
1.2 Files, directories
1.3 Login, logout
1.4 Command Processor, subsystems
1.5 Names, objects, name spaces, access locks, access keys
1.6 Command processor name space, BEAD name space, SCANL, PERMDIR, TEMPDIR, OWN.KEY, null key, PUB.KEY
1.7 SERVICES, BEAD GHOST, errors
1.8 Space control (what to do about 6,?,?? errors)
1.9 'WHO' and PANICS, or how to untangle a console and how the user stops something he wishes he hadn't started
1.10 A note on the Line Collector (how to erase mistakes)

2. Examples

2.1 Use of BASIC, not keeping permanent files
2.2 Creation of a permanent disk file to be kept for future sessions:
   2.2.1 future access 'automatic'
   2.2.2 future access 'manual'
2.3 Access to permanent disk files
   2.3.1 Using BASIC on the file from example 2.2.1
   2.3.2.1 Selective access to permanent files
   2.3.2.2 Making all the user's permanent files available to all subsystems
2.4 SCOPE Simulator: a simple interactive FORTRAN program
2.5 SCOPE Simulator: an interactive SNOBOL program using a file from a friend's directory
2.6 Login problems illustrated

3. Subsystem summaries

3.1 EDITOR
3.2 BASIC
3.3 SCOPE
3.4 SERVICES and the BEAD GHOST
PREFACE

This document is intended to provide inexperienced users with quick and easy access to many CAL TSS facilities. It is not intended to be logically complete or fastidiously accurate.

The first part gives a brief description of the logical structure of the system as seen by the user. The second part is a collection of examples of some useful interactions. The examples provide a cookbook approach which may be adequate for some users, and it is hoped that the section on general concepts will be helpful in easing the user into productive and flexible use of the system. However it is doubtful that these pages will answer all questions or transform someone with no previous experience into a proficient user without some work.

Fortunately, one need not be an expert to use the system. One of the advantages of interactive systems is that the user can "try it and see if it works" without incurring a prohibitive cost in money or time. Thus, a light reading of this document should be more than enough to prepare the user to start experimenting on the system itself. Of course, having assistance from someone who knows CAL TSS is very helpful. But in the absence of expert advice, going back and forth between the examples, the console, and the description of general concepts is hopefully a reasonable route to expertise.

The third section gives brief summaries of the subsystems available on CAL TSS. These summaries are not intended to teach people how to use the subsystems. Rather, they are intended as convenient "crib sheets" for people who already know how to use them.
1.1 Access to CAL TSS

To use CAL TSS, one must satisfy two requirements. The first is to make arrangements with the Computer Center accounting office, or a TA, or some such authority who has time to dispense. He will provide the name of a permanent directory which will pay for use of the system, and a password, which will verify the right to use that directory. The second is to have access to a teletype (or other teletype compatible terminal), connected to the 6400 B system. It is assumed that the reader has access to such equipment and knows how to operate the equipment itself. Below are noted a few useful features of keyboard input to CAL TSS:

a) input lines are terminated by the RETURN key (no line feed)
b) typing CTRL-Q erases the previous character entered
c) typing CTRL-Y erases all characters in the current line
d) typing CTRL-I skips to the next tab boundary (cols 11, 21, ...)

1.2 Files and Directories

Files are system-maintained objects in which a user can keep information (source code, programs, data, etc.). In particular, when a user is not active on the system, virtually all the information he wants to keep is stored on the disk in files. Directories keep track of the names and locations of all the files in the system, plus various other information. Each user has his own directory which keeps track of his own personal files and contains information pertaining to him. This directory stays on the disk when the user is not active and is called the user's permanent directory to distinguish it from other directories which are described later.

1.3 Login, logout

The process of making contact with CAL TSS is called LOGIN. The user tells the system he is present by typing CTRL-SHIFT-P on the console. The system then starts to construct the machinery necessary to give him access to his files and to the various subsystems available to manipulate files. Nominal amounts of system resources are reserved for him. This nominal amount is sufficient to run a small BASIC program or to use the EDITOR to modify a text file. The console responds by asking the user to name his permanent directory and to prove that he is authorized to use it by giving the password.

A temporary directory is then created to hold the files that come and go as he uses the system. The console asks him to name his temporary directory. Since this name will be used globally across the system, it must not be the same as someone else's temporary directory (if it is
the same name as another's, the user is then asked to choose a different name. The appearance of the Command Processor signals successful completion of the LOGIN procedure.

The temporary directory and any files which it owns will be destroyed when the user finishes using the system and logs out. It is easy to logout: simply get into the Command Processor and type 'LOGOUT' (see examples).

Note that once the user has successfully logged in, he starts being charged for the resources necessary to be active on the system. This charging will stop only after LOGOUT (not when the console is turned off).

1.4 Command Processor, subsystems

When the LOGIN procedure is completed, the user will be talking to the Command Processor. The Command Processor does not do many things for the user itself, rather, it accepts commands to set up various subsystems to work for him. Some standard subsystems which are always available on the system are introduced in Table 1. A user may also code and call (through the Command Processor) his own subsystems. The exact method of doing this is not described here.

<table>
<thead>
<tr>
<th>SUBSYSTEM NAME</th>
<th>WHAT IT DOES</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDITOR</td>

<tr>
<td>SERVICES</td>
<td>manually manipulates user's files and directories.</td>
</tr>
</tbody>
</table>

The Command Processor and all the subsystems print some character at the beginning of the line when they are ready to accept a command. This is called a prompt character. A table in section 1.9 shows the different prompt characters for all the system-provided subsystems. After the Command Processor prompts, the user might tell it
intending to edit a file called 'input' (the ! at the beginning of the line was typed by the Command Processor, not the user). A general example of the form of commands accepted by the Command Processor is

```
!command param param ... param
```

where **command** and **param** are strings of characters separated by spaces. How the Command Processor turns the characters at the console into internally meaningful information is a long story, which is introduced next.

### 1.5 Names, objects, name spaces, access locks, access keys

When the user types

```
!EDITOR INPUT
```

to the Command Processor, 'EDITOR' and 'INPUT' are examples of what are called **names** in this document. The handling of both these names makes use of the concept of **name space**. The trick is to turn a string of characters into some internal form which will give access to a file or a subsystem. A name space can be thought of as a dictionary which translates a string of characters (name) into the required internal form. There are several different types of internal forms all of which are referred to as **objects**. Files and directories are examples of objects. A directory contains the names of objects and also information about those objects. Thus, one form of name space is a sequence of directories to be searched in turn for the given names.

Another important concept in changing names into objects is that of an **access_key**. A given name in a directory may be shared by having an **access_lock** attached to it. In order to get access to the named object, an **access_key** must be presented along with the name. Access locks not only control whether or not access is permitted, but also what kind of access is permitted. Thus, a given file name in some directory may be protected with two different access locks such that when it is looked up with one key, the file may only be read from, while it may be read, written, or destroyed if it is looked up with the other key.

The most common form of name space is a sequence of pairs (directory, access key). The scope and power of a given name space are determined by what directories are searched and what access keys are used.

There are several different name spaces attached to each user, and different ones are used in different circumstances.
The first parameter typed to the Command Processor is looked up in the command processor name space (see Table 2). PERMDIR is a name used to refer to the user's permanent directory, TEMPDIR is a name used to refer to his temporary directory. PUBLIC is the name of a directory which contains the names of all system-provided subsystems. For example, it contains the name 'EDITOR'. If the user has just typed: 

!EDITOR INPUT

the Command Processor is guaranteed to find the name 'EDITOR'. Having found the object named EDITOR, the Command Processor assumes that the object is a file which it can use to construct the EDITOR subsystem. It proceeds to do this. Note that if a file named EDITOR were in the user's temporary directory, the Command Processor would find that file because it searches TEMPDIR first. It would then try to start up a subsystem constructed from the user's file, which is fine if the file contains the user's own private version of the EDITOR. Otherwise, an error results. It is always best for the user to know what he is doing before he tries it.

The interpretation of the parameters after the first one is dependent on the subsystem being called; each subsystem specifies the name space it uses to evaluate parameters. The three possible name spaces are shown in Table 2. The HEAD name space is an old form left over from previous incarnations of the system. It is being phased out. The SCANL name space is initially as shown in Table 2, but the user may modify it to suit himself.

Much of the complexity of the name space situation stems from considerations about the sanctity of permanent files (owned by the permanent directory) and the reliability of subsystems. Consider the nature of the files in the user's permanent directory as opposed to the nature of the files in his temporary directory. Many subsystems use temporary or scratch files which are not of interest to the user. These files come and go in TEMPDIR without troubling the user. They automatically disappear when he logs out. Free access to these files is essential to the operation of the various subsystems. Presumably it is no great loss if a subsystem runs wild and a temporary file gets clobbered. PERMDIR, on the other hand, gives access to the user's permanent disk files. The user would be justifiably annoyed to discover that one of his files had been used as a scratch file by some subsystem. There is no automatic backup of these files. If some subsystem has access to a user's files and uses one for scratch or goes wild and destroys files, he is in trouble. His files are gone, and it will be monstrously inconvenient and expensive to recover them. Therefore the system does not automatically allow access by subsystems to the files in the permanent directory. If the user trusts all the subsystems he is going to call, there are ways he can grant those subsystems access to files in PERMDIR (see 2.2-2.3), but great caution
is advised. It is as though those files were the only copy of the information.

One difference between the various name spaces is indicated by the access key used when looking in the permanent directory. The null key can only be used on one's own directories (PERMDIR, and TEMPDIR in most cases of interest). It gives unrestricted access to any file in those directories. OWN.KEY is the user's personal key which was created along with his permanent directory. It is unique to him, unless he gives it away. The user may grant access to a given file in his permanent directory from name spaces less powerful than the command processor name space by attaching an access lock matching OWN.KEY to the file. The access may be restricted (to read only access, for example) by turning off suitable 'option bits' in the lock one puts on the file (see examples). PUB.KEY gives read only access to the files in the PUBLIC directory.

Now it may be clear that there must be at least two name spaces. On the one hand, unrestricted access to the files must be possible, otherwise the user might not be able to do something with his file that he wants to do. On the other hand, there must be name spaces which keep unreliable subsystems from wreaking havoc. The existence of more than two name spaces is an unfortunate historical accident.

The existence and use of the name spaces is complicated by compatibility features for subsystems following the conventions of an extinct early version of the system. For both 'old' and 'new' subsystems, the command name is looked up in the command processor name space, but the processing of the subsequent parameters varies.

Old subsystems have all parameters looked up in the BEAD name space. During execution, they may request further objects from the Command Processor, which are also looked up in the BEAD name space. All existing subsystems are being converted to the new conventions as quickly as possible.

New subsystems have their parameters looked up in the command processor name space. During execution, they may request further objects in two ways. If the subsystem makes up the name of the object, it is looked up in the SCANL name space. Objects may be obtained from the command processor name space only if the user types in the name from the TTY. Thus, in either case, permanent files are protected from unruly subsystems and from accidental use as scratch files.
For use of CAL TSS beyond the trivial, a knowledge of these two special subsystems is required. SERVICES and the BEAD GHOST are similar to normal subsystems, but are actually just new 'hats' donned by the Command Processor appropriate to the occasion.

SERVICES is a general utility subsystem allowing manual manipulation of files, directories, etc. The main reason for removing this function from the Command Processor proper is to minimize the number of reserved words which may not be used as names of user subsystem ('SERVICES', 'LOGOUT', etc.).

Unlike SERVICES, which is troublesome because it must be called, the BEAD GHOST is annoying because it appears without being called. The BEAD GHOST is the system debugger and its appearance is prompted by some error. Whenever a subsystem makes a mistake in dealing with some object or some part of the system, error processing is initiated. Some errors are handled automatically by various subsystems along the way.

---

1. methods for altering SCANL from the console are available.
2. The BEAD NAME SPACE really occurs in several forms. This is the most common form. Other forms are not of crucial interest and are not described here.
and the user isn't even aware of them. Many are reported to the console by a given subsystem to indicate that they were asked to do something illegal or impossible (the Command Processor is an outstanding example of this). Some represent unforeseen circumstances for which no remedial procedures have been provided (called 'bugs' for short). They are reported to the console by the BEAD GHOST in hopes that the user will know what to do (like complain to a system programmer). Currently, only class 6 errors ("6,n,m ERROR") should be reported to the console by the BEAD GHOST under normal circumstances. Other appearances of the BEAD GHOST should be reported, along with all the relevant console printout, to the system staff.

Class 6 errors mean that the resources reserved for the user have become inadequate for the task being performed. When they occur, the user must either obtain additional resources or abort what he was doing, which introduces the next topic.

1.8 Space Control

CAL TSS has several types of storage for which there is currently no automatic algorithm for sharing the available space among the users. The only positive thing to be said for the scheme described below is that it is better than simply handing out space until it is all gone and then letting the system grind to a halt (or crash).

<table>
<thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>

When a user logs on, he is allocated the nominal amount of space of each type. A command is available to obtain space in excess of this amount. If a user requests an amount of space larger than what is currently available he is put into a queue waiting for someone to release space. If the request is for more space than the moderate limit, he is put in a special queue which prevents more than one user at a time from being "very large" in any particular type of space.

There is currently no mechanism to force a user to release space once he has it. Several mechanisms tend to prevent space hogging. First, whenever a user returns to the Command Processor, he is automatically
reduced to nominal. Last, a user who has space over the nominal in some category is not allowed to get more space in that or any higher category without first releasing his space and going to the back of the queue.

The space command works as follows and may be typed to the BEAD GHOST or to SERVICES:

```
SPACE p1 p2 p3 p4
```

$p1$ through $p4$ are the amounts of swapped ECS space through temporary disk space, respectively, that are desired. The following algorithm is executed for each parameter starting with $p4$:

- if $p4 = -1$ : space of this type is released to get down to nominal if possible
- if $p4 = 0$ or not typed (trailing parameters): ignored
- if $p4 > 0$ :
  1) If space above the nominal for that type or higher type has been obtained, error.
  2) If parameter is higher than maximum permitted for this type, error.
  3) If parameter greater than moderate limit, enter very large queue.³
  4) If parameter less or = nominal, no further action.
  5) Otherwise, accumulate this type of space until the amount this user has is up to the size of the parameter, waiting in queue if necessary.³

There are two different starting points from which the user may find himself requesting space:

1) He is about to call a subsystem and knows in advance how much space it will require: enter SERVICES and request the required amount of space and then go back to the Command Processor and call the subsystem. The request has to be big enough - see below!

2) A subsystem he has called runs out of space and makes a class 6 error which invokes the BEAD GHOST: if he has not already requested space, the user may do so now with the space command. After he has gotten the space, he types RETRY (not RETURN) and the subsystem will resume. If he already has space, there is no way for him to save himself - he must type

³ A message will print if the space is not immediately available - a panic (see 1.9) will remove the user from the queue if he would rather not wait.
Purge, which aborts whatever work the subsystem may have done for him, and start over in the Command Processor.

1.9 WHO and PANICs (How to untangle a console and how the user stops something he wishes he hadn't started)

WHO is a request that may be typed at the console to determine which subsystem is in control. PANICs are a way of interrupting whatever is going on if the user has somehow lost control. PANICs come in two flavors:

MINOR PANIC (or PANIC for short) - hold down the CTRL and SHIFT keys and simultaneously type P to send a minor PANIC;

MAJOR PANIC - hold down the BREAK key for at least three seconds to send a MAJOR PANIC

The difference between a PANIC and a MAJOR PANIC is that subsystems may handle PANICs on their own if they wish to, but a MAJOR PANIC always invokes some arm of the Command Processor.

The remainder of this section gives three procedures covering different cases of console problems, plus a table telling how to recognize and/or dismiss subsystems.

PROCEDURE I covers how to approach a console initially.

PROCEDURE II tells what the user does if he is already logged in and using the console but has either forgotten what he was doing or the console stopped responding the way he expects it to.

PROCEDURE III is for those times when the user has started something that he wants to stop (e.g., the EDITOR is printing 2000 lines because he mistyped something or his BASIC program has been computing silently for an ominous length of time, etc.).

Sometimes the relevant procedure has a happy ending and the user can continue. But, alas, the procedure may suggest that the console is down, or the system is down, or there is a bug in the system. The user can frequently distinguish between a sick console and a sick system by seeing if other consoles in the area are operating. If they are, it looks like the console is sick. If they aren't, it looks like the system is. The current procedures for reporting troubles of this nature should be available from some other sources. They are not included here because they are in a state of flux.
PROCEDURE 1 - a user is just approaching a console to try to establish contact with CAL TSS

---

Make sure the console is on and is connected to CAL TSS.

Make sure CAL TSS is supposed to be available at this hour of the day.

Make sure somebody else isn't using this console.

Send a PANIC.

response

no

response

Send a MAJOR PANIC

response approximately equal to

CAL TSS VERSION something

PERMANENT DIRECTORY?

no

response

no

yes

Are you really sure the console is OK?

yes

It looks like your console is down or the system is down.

Response say something about no space?

no

yes

This means that the console was already logged in

(Perhaps that man hurrying across the room with his cup of coffee will shed some light on the situation). This is your problem. You can PUGE the guy and log him out if that is your style or try to find him if you are more solicitous.
PROCEDURE II - the user is logged in and using the console and has either forgotten what he was doing or gotten into some mysterious state where the console doesn't respond the way he expects it to:

| REMEMBER THAT ALL INPUT LINES END WITH A CARRIAGE RETURN |
| (THE KEY MARKED RETURN ON TELETYPES)!!! |

| If you haven't already done so, look up the prompt character in the table. (Subsystems signal that they are ready to process a request by printing a character at the beginning of the line. The table will help you identify the subsystem if there is a prompt character visible.) |

| no |
| If you have just typed something, did the characters echo (print)? |
| yes |
| If the lines are being happily swallowed by the console and no prompt characters are appearing, some subsystem is gobbling them up. Are you perhaps in insert mode in the EDITOR or BASIC? You get out of that mode by entering an empty line (no characters, just the RETURN key.) If you were in insert mode and you enter an empty line, a prompt character should appear and you can go from there. |

| Type WHO (followed by RETURN, of course). |
| no |
| response |
| response |

| Civilized subsystems respond to this query by announcing their name. Barbaric subsystems are likely to treat it as a nonsense command and print some irrelevant diagnostic. In either case, the table should tell you what's going on. |

| Send a PANIC |
| no |
| response |
Some subsystems field (minor) PANICs and allow you to resume control. Others duck the PANIC and the BEAD GHOST appears. You can tell the BEAD GHOST to abort the subsystem by saying PURGE and you will get back to the Command Processor. (You can also poke around in the subsystem with the BEAD GHOST if you are debugging it, but that is fairly sophisticated.)

Send a MAJOR PANIC

no

response

It looks like your your console or the system is down.

A subsystem which swallowed PANICs was in execution. No system-provided subsystem should behave this way. Either it was a non-standard subsystem, or CAL TSS has a bug.
PROCEDURE III - the user has just started something he wishes he hadn't

1. Send a PANIC

<table>
<thead>
<tr>
<th>no response</th>
</tr>
</thead>
</table>
| Nice subsystems will stop what they're doing and wait for the user to tell them to do something else. Not-so-nice subsystems will duck the PANIC and the BEAD GHOST will appear. The user can abort the subsystem and get back to the Command Processor by typing PURGE. Or if he decides that whatever was going on was OK after all, he can tell the BEAD GHOST to make the subsystem continue exactly what it was doing when interrupted by typing RETRY.

2. Send a MAJOR PANIC

<table>

1.10 The Line Collector

Unless the user does something extraordinary, all console input goes through a piece of software called the Line Collector, which provides a large number of ways to correct/change the line being entered. The chart below indicates the various manipulations that can be performed; to invoke a given function, hold down the CTRL key and type the relevant key. A detailed explanation is available in the "Users Guide", sec. III.2.3. Here we give two examples and encourage the user to experiment. Underlined characters represent one key or a combination of keys, not the sequence of keys given by the individual underlined characters; blanks that might otherwise be "invisible" are also underlined.

First note that the Line Collector maintains the previously typed line as the old line and uses it, in conjunction with typed characters, to construct a new line. Whenever the new line is accepted (by typing RETURN, for example), it becomes the old line.

Suppose the user is talking to BASIC and has just entered the line (considered as the old line) below (which will have provoked a message from BASIC objecting to the line).

old line: PRNIT X

type meaning and the teletype responds
CTRL-L make an insert at the beginning of the old line <
10 this is what is to be inserted 10 PRNIT X
CTRL-O copy the rest of the old line (all of it) into the new line and accept the new line.

BASIC will issue another diagnostic as it still will not recognize the line as a valid statement.

old line: 10 PRNIT X

type meaning and the teletype responds
CTRL-D copy the old line into the new line up to the first occurrence of the next character typed no response
IM you wanted IN and made a mistake IM
CTRL-O erase the M <-
N
CTRL-H copy the rest of the old line into the new line T_X
July 1971

RETURN you are satisfied with your new line

BASIC should accept this line, which is old line: 10 PRINT X,Y

2. Examples.

These examples are not all-inclusive. They are provided to give a feeling of how CAL TSS works, plus a few pointers on how to do some commonly useful things. The first example is heavily commented, subsequent ones are commented only where they contain points of special interest. Characters typed by the system have been underlined in the first example to distinguish them from the things that the user typed. Subsequent examples are not underlined.

EXAMPLE 2.1 - SIMPLE USE OF BASIC, NC FILES KEPT

1.0 These lines constitute the login procedure. Prior to the first line, the user has attracted the attention of CAL TSS by typing P while holding down the CTRL and SHIFT keys.

1.1 'GUEST' is the name given for the permanent directory.

1.2 The password to use the GUEST directory is also 'GUEST', but the password is not usually the same as the directory name.

1.3 'JOHN' is the name the user chose to give to the temporary directory.

2.0 The appearance of the Command Processor signals the successful completion of the login procedure.

2.1 The user tells the Command Processor that he wants to use the BASIC subsystem.

3.0 All these lines are a conversation with the BASIC subsystem.

3.1 BASIC announces its presence and signals that it is ready to process commands by printing '-'.

3.2 The user gives it an immediate command to print the value of pi and it responds with the value.

3.3 Now the user decides to construct a simple BASIC program, so he begins entering indirect statements. These lines constitute the text of the BASIC program being constructed.

3.4 This is an example of erasing a mistake. The arrow printed because the user typed CTRL-Q to erase the 9. The actual line entered was '20 LET Y = 18'.

3.5 The user forgot a comma in this line, so BASIC does not recognize it as a valid statement and complains. The correct line is entered.

3.6 The user tells BASIC to run the program he just constructed and it runs the program and prints the results.

3.7 He decides to change the program and types the request 'LIST 30', which types line 30 for inspection.

3.8 The user tells BASIC that he is going to edit that line, so it is made the old line in the Line Collector.

3.9 This line was constructed by typing CTRL-H, which copied all of the old line, and then typing ',X/Y' followed by RETURN.

3.10 The user now runs his program again and the new results appear.

3.11 The FIN command tells BASIC that the user is finished. BASIC warns the user that changes have been made in the program which will be lost if the user does not use the SAVE command to save the new program. The user repeats FIN to inform BASIC that he does not wish to save the program he has constructed.

4.0 The Command Processor resumes control of the console.

4.1 The user signals that he is finished using the system by typing 'LOGOUT'. The system prints the accounting data for the run and after it wishes him a good day, the console goes dead.
This page no longer contains information.

EXAMPLE 2.2 - CREATION OF PERMANENT DISK FILES TO BE KEPT FOR FUTURE SESSIONS

1.0 This is the login procedure again, except that the permanent directory name is 'USER:V' and the password is 'QRBL'. 'V' has been chosen as the name for the temporary directory.

2.0 The user tells the Command Processor to call the subsystem SERVICES.

3.0 These lines are a conversation with SERVICES.

3.1 The user requests SERVICES to make a new disk file by saying NEWDF. He has asked that it be created in his permanent directory and named AUTO.

3.2 The command 'PCAP OWN.KEY' causes the user's private access key to be displayed. This is done so that he can see the number of the access key, which is required by the command which adds locks to names. The number is the 53002 which occurs in the second line.

3.3 This command adds lock 53002 matching his OWN.KEY, to the file AUTO in his PERMDIR. The string of 7's are the kinds of access which the user is allowing, namely all kinds of access. The addition of this lock to the name 'AUTO' makes the file AUTO available in the BEAD name space, and it will automatically be available whenever he logs on in the future.

3.4 A mistake was made in entering this line; the first 'I' was erased by typing CTRL-G. The line actually entered was 'NEWDF PERMDIR:MANUAL', which creates a new file MANUAL in the user's PERMDIR.

3.5 Because the user decided not to have automatic access to MANUAL, he set up a name in TEMPDIR which can be used to access MANUAL during this console session. The sense of this command is to allow the file MANUAL in PERMDIR to be referred to as M in TEMPDIR.

3.6 This dismisses SERVICES and the Command Processor returns.

4.0 The Editor is used to put some text in the files AUTO and MANUAL, alias M, for future sessions.

EXAMPLE 2.3.1 - USE OF A PREVIOUSLY CONSTRUCTED FILE IN BASIC

1.0 Only the interaction with BASIC is described, although the reader should note that no special manipulations were done after login to get access to AUTO.

1.1 The command 'LOAD AUTO' tells BASIC to load the file AUTO.

1.2 The user may not have noticed the mistake made when constructing AUTO, but BASIC does notice. It prints a diagnostic message followed by the offending statement.

1.3 After BASIC has read the whole file, it prompts again. The user tells it to list the program.

1.4 The program is printed and he sees that the statement in error has been left out.

1.5 This is the correct form of the statement.

1.6 He asks that the program be run and the results are printed out.

1.7 Because the user made a correction to his program, he wants to save the new version, so he does a 'SAVE'. The FIN leaves BASIC destroying the program in it.

EXAMPLE 2.3.2.1 - SELECTIVE MANUAL ACCESS TO PERMANENT FILE

1.0 This shows that the Editor wasn't given a copy of the user's file MANUAL, because he printed the file and it is empty.

2.0 The user talks to SERVICES to set up access to MANUAL.

2.1 This command sets up access to MANUAL in his PERMDIR under the name 'M' in TEMPDIR.

3.0 He calls BASIC, reads in his file MANUAL, alias M, and executes the program.

EXAMPLE 2.3.2.2 - ACCESS FOR SUBSYSTEMS TO ALL YOUR PERMANENT FILES

1.0 This conversation with SERVICES makes the user's PERMDIR look like part of his TEMPDIR and hence gives access to his permanent files to all subsystems which have access to the temporary files.

1.1 CHAIN causes the first directory, PERMDIR, to have the second directory, TEMPDIR, appended to it. Oops, that's backwards.

1.2 So UNCHAIN takes any appended directory out of PERMDIR.

1.3 Now CHAIN appends PERMDIR to TEMPDIR, which is what the user was trying to do. If he hadn't unchained PERMDIR from TEMPDIR back at step 1.2, the two directories would constitute a loop and the code which looks up names would get annoyed if it ever used them.

2.0 The same use of BASIC as in the previous example.

EXAMPLE 2.4 - SCOPE SIMULATOR: A SIMPLE INTERACTIVE FORTRAN PROGRAM

This example was generated when the system was fairly busy. When the user tried to log on, he was refused access because there was no space to accommodate him. The space fluctuates on a short time scale, so the user just kept trying until he got on. Subsequently, the SCOPE subsystem requested additional space which was not immediately available and CAL TSS printed the messages saying 'waiting at top of queue...' and 'waiting for access to...' so that the user would be forewarned that processing his request might take longer than usual.

1.1 The reader has seen this before. The file TRIVIA in PERMDIR is made available in TEMPDIR as INPUT.

2.0 The file is printed with the Editor.

2.1 Notice the special file names used to talk to the console.

3.0 The user asks for the SCOPE Simulator. Characters typed by the user are underlined in this section.

3.1 SCOPE requests the SCOPE Simulator and the 40000 is an optional parameter which determines the initial FL in the Simulator. If it is omitted, a default value of 14000 is used. 40000 is required to use the RUN compiler so that is why this value was chosen. SCOPE prints the time and date.

3.2 > is SCOPE's prompt character, signalling that it is ready to process a request. The user may type the same commands that he would have put on his control cards when using the batch system. In particular, RUN causes the FORTRAN compiler to compile statements from the file INPUT.

3.3 Another command causes the compiled program to be loaded and executed.

3.4 The previous line was printed by the user's program. The ↑ is the prompt character which signals that a program running on the simulator is waiting for input, as opposed to the simulator itself. After the user responds 'GEORGE', (followed by RETURN, of course), the program grinds to its rather uninspiring conclusion and SCOPE starts watching the console again.

3.5 SCOPE prompts for another command and the user dismisses it. The Command Processor reappears.

GOOD DAY
EXAMPLE 2.5 - SCOPE SIMULATOR: AN INTERACTIVE SNOBOL PROGRAM USING A FILE FROM A FRIEND'S DIRECTORY directory

This rather complicated example involves four separate console sessions.

1.0 The whole purpose of this session is to find out the number of the user's access key so that his friend can add it to the files she wants to let the user use.

1.1 The user tells SERVICES to print OWN.KEY so that he can see its number, which is 123401.

2.0 This session is done by the user's friend, in order to add locks matching the user's key to her files.

2.1 These commands to SERVICES add locks matching his key, which is 123401, to his friend's files REACT and DATA in her permanent directory. Only read access is allowed by the option lists 71420.

3.0 Now the user is going to make links in his own permanent directory to his friend's files.

3.1 This is an example of typing first and thinking later. None of these commands did anything except provoke nasty messages from SERVICES.

3.2 Finally, FRIENDP causes a search to be made for a permanent directory named 'USER:VV', and if one is found, a link to it named 'VV' will be placed in TEMPDIR. If a permanent directory USER:VV isn't found, the user will get some message like the ones printed above.

3.3 These commands make links in PERMDIR named 'REACT' and 'DATA' to files REACT and DATA in the directory VV. The meaning of 'VV:REACT:OWN.KEY' scans roughly as: find something named 'VV', (which will be the permanent directory of the user's friend USER:VV) and look up file REACT in that directory using the access key OWN.KEY.

3.4 These commands have been seen before. They give automatic access in the future to the files named by 'REACT' and 'DATA' in the user's permanent directory. Even though the locks added here would allow all kinds of access, read only access is all that is allowed because of the locks on REACT and DATA in USER:VV.

4.0 This session uses the files to which the user has laboriously gained access. It is program written in SNOBOL which interacts with the console and writes poetry.

4.1 The user calls SCOPE and invokes SNOBOL on his file REACT.

4.2 Most of the rest of this example is a conversation with the poet. Lines which start with the ↑ indicate that the poet is waiting for the user to say something and the characters after the ↑ are whatever the user chooses to respond.

4.3 When interest in poetry wanes, the poet goes away and SCOPE resumes watching the console. The user leaves much edified.

EXAMPLE 2.6 - LOGIN PROBLEMS ILLUSTRATED

1.0 When the user sent his CTRL-SHIFT-P to CAL TSS, there wasn't enough space to accommodate him. The space in the system fluctuates on a fairly short time scale, so trying again every few seconds will generally get the user on before he can get annoyed.

2.0 This interaction illustrates the consequences of most of the mishaps that can occur during login.

2.1 'UNEXPECTED RETURN' means that there is not a permanent directory named 'VV'.

2.2 'BAD SYNTAX' indicates that 'USER:VV;' is not even a possible name for a permanent directory.

2.3 Self-explanatory.

2.4 'DUPLICATE TEMEDIR' means that someone else has already named his TEMEDIR 'PAUL'. The user must keep choosing a new name until he gets one that does not conflict.
3.1 **Summary of the Editor**

The Editor subsystem enables the TSS user to construct and edit files of coded information. A **file** consists of lines, where a line is a string of coded characters ending with a carriage return character (generated by the RETURN key on the teletype).

The Editor is called by typing a command of the form:

```
EDITOR fname
```

where **fnname** is the name of the file to be created and/or edited. All file names are looked up in the BEAD name space. The Editor prompts by typing `:` and awaits a request. At any given time the Editor is looking at a specific line called the current line. When the Editor is first called, the current line is a pseudo-line which is always the top line of every Editor file.

The following requests may be typed to move about the file for the purpose of creating, deleting, or editing text lines. Each request is terminated either by a carriage return or, if more than one request is made on one line, by a semi-colon. Some requests contain a "stop condition" or **line specifier**, represented by *sc* below. Such requests affect all lines from the current line to the line specified by *sc*, inclusive. (If you've lost track of the current line, request 'P' and the Editor will print it.) *sc* may be:

1) a decimal number, specifying the line that number of lines from the current line,
2) `.str` (where *str* is any string of characters except semi-colon), specifying the next line containing the string of characters,
3) `/str`, specifying the next line starting with the given string of characters, ignoring leading blanks,
4) `$`, specifying the bottom, or end, of the file,
5) omitted, specifying the current line.

After the Editor has processed the request, the line specified by the request becomes the new current line.

<table>
<thead>
<tr>
<th>Requests</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Insert, after the current line, the lines which follow. Insertion is ended by entering a null line (carriage return only). Delete the specified lines.</td>
</tr>
<tr>
<td>T</td>
<td>Move to the top of the file (pseudo-line). Move forward over the specified lines.</td>
</tr>
<tr>
<td>Bsc</td>
<td>Move backward the specified number of lines. (NOTE: <em>sc</em> can only be a number.) Print the specified lines.</td>
</tr>
<tr>
<td>Psc</td>
<td>Replace the first occurrence of <em>str1</em> by <em>str2</em></td>
</tr>
</tbody>
</table>
in the specified lines.
Replace every occurrence of \texttt{str1} by \texttt{str2} in
each of the specified lines.
\texttt{Edit} the specified lines using the Line
Collector.\textsuperscript{*}

\begin{itemize}
\item \texttt{R,\textit{fname}}
Insert the contents of the file \texttt{fname} after
the current line.
\item \texttt{W,\textit{fname},sc}
Write the specified lines, including the cur­
rent line, into the file \texttt{fname}.
\item \texttt{F,\textit{fname}}
Finished - create the file \texttt{fname} from the
latest version; simply entering 'F' causes the
updated text to replace the original file
specified when the Editor was called.
Finished but do not save any file.
\end{itemize}

The Editor prompts with : and response ???? to lines it does not
understand.

\begin{itemize}
\item Each line being \texttt{edited} is made the old line in the line collection
and may then be altered using the Line Collector. (See section 1.10 on
the Line Collector.)
\end{itemize}
3.2 Summary of BASIC

BASIC is an easy-to-learn, general-purpose programming language similar to FORTRAN but created specifically for time-shared computing environments. For details see the description in the CAL Computer Center Users Guide, available at the Computer Center Library.

BASIC accepts two types of statements: 1) indirect, which are saved to be executed sequentially as a program at some other time; 2) direct, which are carried out (executed) as soon as they have been entered using the carriage return key (direct statements, especially the PRINT statement, allow the teletype to be used as a very powerful desk calculator).

Although some statements may be used only directly (or indirectly), most statements may be used either way. All indirect statements must begin with a line number and are executed in order of ascending line numbers. Those without line numbers are assumed to be direct. Statements which may be indirect only are those that would only make sense in a program. Statements which may only be direct are usually for changing the program itself rather than the data it works on.

BASIC is called by typing a command of the form:

BASIC name

where name, if specified, is a file containing a BASIC program to be loaded. BASIC responds with BASIC VERSION ... after which either direct statements or a program of indirect statements may be entered.

BASIC prompts with -.

There are three ways to enter a program of indirect statements:

1. Pass BASIC a file name as the first parameter when it is called; the file is loaded in the same manner as when a 'LOAD' command is given.

2. Use the 'LOAD' command to read in a program from a file. Lines containing errors will be typed out after an error message and are not included in the program.

3. Create a new program by typing it into BASIC. Lines with errors will not be saved.

Sample BASIC program starting from the Command Processor:

BASIC
100 PRINT "NUMBER", "SQUARED", "CUBED"
105 PRINT
110 FOR X=1 TO 10
120 LET S=X*X
July 1971

```
130 PRINT X*S,X*S
140 NEXT X
150 END
RUN
```

<table>
<thead>
<tr>
<th>NUMBER</th>
<th>SQUARED</th>
<th>CUBED</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>9</td>
<td>27</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>64</td>
</tr>
<tr>

</tr>
<tr>
<td>9</td>
<td>81</td>
<td>729</td>
</tr>
<tr>
<td>10</td>
<td>100</td>
<td>1000</td>
</tr>
</tbody>
</table>

**EXECUTION COMPLETE**

Now the user may:

1. Edit his program using direct statements and rerun it.
2. Quit (and return to the Command Processor) by typing FIN.
3. Save his program by typing SAVE *name*.

**List of Indirect or Direct Statements**

- **LET var=[...var=]expr**
  - Each variable\(^5\) takes on the value of the expression.
    - Example: 10 LET A=4.35-F

- **DIM array(dim list)[,...,array(dim list)]**
  - Reserve space for arrays with more than two dimensions and/or dimensions > 10.
    - Example: 20 DIM A(60),L(5,N,3*N)

- **SIG expr**
  - Number of significant digits printed for numbers is changed to the value of expr.
    - Example: 30 SIG N

- **DEF FN letter(param)=expr**
  - Defines a one line function whose name has three letters starting with FN and whose single dummy parameter is param.
    - Example: 35 DEF FNG(X3)=X3/10 - A0/X3

- **READ var[,...,var]**
  - Reads from a DATA defined list and assigns values to the variables

---

\(^5\) A variable may only be a letter optionally followed by a digit, or by a list of expressions separated by commas and enclosed in parentheses.
Requests input values from the TTY by typing ? and assigns values to the variables in sequential order.

Example: 12 INPUT A,B,C

PRINT [ ... ITEM]
Prints and/or moves the teletype head as indicated by the item(s) which may be num expr, string var, 'characters', TAB(expr), ;, and :.

Example: 100 PRINT "VALUE ", TAN(B1*B1)

RESTORE
Restores the pointer into the DATA bank to the top.

IF log expr GOTO lnum
IF log expr THEN lnum
Transfers control to the statement with line number lnum if the logical expression is true.

Example: 105 IF A>B/SIN(X) GOTO 115

GOTO lnum
Transfers control to line number lnum.

Example: 20 GOTO 300

ON expr GOTO lnum[ ... lnum]
If expr has value=1, GOTO statement having first lnum in list; if expr has value 2, GOTO statement having second lnum in list, etc.

Example:
10 LET X=1
20 ON X GOTO 30,40,50

REM char string
A comment statement.

GOSUB lnum
Go to the statement specified by the line number but return to the line following the GOSUB when a RETURN statement is encountered.

MAT READ c - Reads values from DATA list into array c.

MAT PRINT c - Prints values from array c.

MAT c = TRN(a) - Matrix c becomes transpose of a.

MAT c = ZFR - Zeros every element in matrix c.
MAT $c = IDN$ - Square matrix $c$ is set to identity matrix.

MAT $c = CCN$ - Array $c$ is set to all ones.

MAT $c = a+b$ - Array $c$ is set to the sum of $a$ plus $b$.

MAT $c = a-b$ - Array $c$ is set to the difference between $a$ and $b$.

MAT $c = a*b$ - Array $c$ is set to the product of $a$ and $b$.

MAT $c = (expr)* b$ - Array $c$ is set to the scalar product of $expr$ and $b$.

MAT $c = INV(a)$ - Matrix $c$ becomes the inverse of $a$.

List of Indirect Statements

**DATA val[...val]**

Forms a list of data values to be used by READ statements.

Example: 12 DATA 5,7.3,30,52

**PAUSE[stf]**

Execution pauses and $stf$, if given, is printed. BASIC will accept direct statements or editing request; execution resumes if CONTINUE is entered.

**END**

Finishes execution; must have highest line number.

**STOP**

Stops execution (acts like a jump to END statement).

**FOR var=exp TO exp[STEP exp]**

NEXT var

Defines the limits of a loop. The three expressions give the initial values of the control variable, the terminating value and the increments, if not equal to 1.

Example: 40 FOR I=1 TO 10 STEP .5
50 LET S=S+I
60 NEXT I

**RETURN**

Execution goes to the line following the last GOSUB for which no RETURN has been executed.

List of Direct Statements

**LIMIT integer**

Specifies a maximum number of statements that can be executed without control returning to the console; prevents infinite loops.
RUN
Causes execution of the program beginning with lowest line number.

CONTINUE
Execution continues where it last stopped.

LIST [line_number[-line_number]]
Prints out the specified lines on the teletype. If the line numbers are omitted or are replaced by 'ALL', then the entire program is printed.

DELETE line_number[-line_number]
Deletes the specified lines from the program. If 'ALL' is typed instead of the line numbers, then the whole program is deleted. Note that this statement has no effect on the values that may have been stored into any variables.

EDIT line_number[-line_number]
The specified lines are passed one at a time to the line collector for editing. Note that if the line number is altered so that it is larger than what it was before but is still smaller than the number of the last line in the range specified, then the line will be edited again when the new line number's turn comes.

LOAD [-line will be edited again when the new line numbers turn comes.]

LOAD [fname]
Loads a program from a text file of the given name. (No lines which may have been entered into BASIC are deleted.) The name, if given, is a simple name which is looked up using the scan list SCANL, created by the system in the user's temporary directory. SCANL looks for the file in the user's temporary directory, his permanent directory (with his own access key) and then in the public directory. To type a more complicated name, fname is omitted and a prompt character quote (") will appear, after which any Command Processor name can be specified.

SAVE [fname]
Writes all the text onto a file of the given name, which must be in the same format as for load. However, if a name is given and no file by that name exists, then a new file is created in the user's temporary directory with that name.

QUIET
Types out BASIC.

FIN
Both of these statements return to the Command Processor after destroying any program that may have existed.
### Operators

**Arithmetic**
- `^` Exponentiation
- `*` Multiplication
- `/` Division
- `+` Addition
- `-` Subtraction

**Relational**
- `=` Equal
- `<`, `>`, `#` Not equal
- `<` Less than
- `<=`, `=<` Less than or equal
- `>` Greater than
- `>=`, `=>` Greater than or equal

**Logical**
- `!` Logical OR
- `&` Logical AND
- `NOT` Logical NOT

3.3 **Summary of the SCOPE Simulator**

SCOPE provides an operating environment for many programs written for CAL's 6400 batch system (SCOPE 3.0 or CALIDOSCOPE), as well as real-time control over the construction and execution of such programs by a user at a console.

SCOPE is called with the following command:

```
SCOPE fl
```

where `fl` is an optional parameter specifying the field length. When omitted, 14000 is the default value. SCOPE responds by typing the date and time and then awaits requests after typing `>`, which is its prompt character. Programs executing under SCOPE prompt with `>` when they want input from the console.

SCOPE creates several standard files necessary for its operation whenever it is called, notably a SYSTEXT file called 'OUTPUT'. Whenever it needs a file to process a request, it gets it from the BEAD NAME SPACE. If there is no file by the appropriate name available, one is created in TEMPDIR.

### SCOPE Simulator Requests

<table>
<thead>
<tr>
<th>Request</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT, <code>fname</code></td>
<td>Declare a new SYSTEXT file <code>fname</code> (will not change to SYSTEXT a file which already exists in another mode).</td>
</tr>
<tr>
<td>FILE, <code>fname</code></td>
<td>Use the file <code>fname</code> as the source of SCOPE Simulator requests.</td>
</tr>
<tr>
<td>MSG, OFF or ON</td>
<td>Suppresses program messages to the console or restarts them.</td>
</tr>
<tr>
<td>GET, <code>fname</code></td>

</tr>
</tbody>
</table>

### Loading requests:

- **L, `fname`**
  - Load and link the file `fname`
- **LGO, `fname`**
  - Load and link the file `fname` and start the resulting code executing
LDCTL,TSS          Set TSS mode for the loader (load all common blocks after program blocks)
OVERLAY,\textit{fname} Contents of loaded and linked core (without banner words) are written onto file \textit{fname}

\textbf{CALIDSCSOF'E Control Requests:}

- SETPRU
- TRACE

\textbf{All RUN FORTRAN Library Routines}
3.4 SERVICES and the BEAD GHOST

This section consists of a list of the commands understood by SERVICES and the BEAD GHOST. An attempt has been made to indicate what sort of parameter(s) each command expects, and some examples of the different kinds of parameters are given below. A few of the commands are understood by only one or the other of the dynamic duo, and they are so marked. The commands are written in caps, the parameters are underlined. The command and the parameters are separated by one or more blanks.

**FIN** is the command which terminates SERVICES; it is not understood by the BEAD GHOST.

**PURGE** (BEAD GHOST only) aborts the current subsystem and returns to the Command Processor.

**RETRY** (BEAD GHOST only) resumes execution of the current subsystem right where it quit.

**RETURN** (BEAD GHOST only) resumes execution of the current subsystem without re-executing the most recent system call, if that call provoked an error.

**NEWPSW password** changes the user’s password to password.

**NEWDF direct:fname** creates a file `fname` in the directory `direct`.

**ADDKEY keynum obits dirolc** adds a lock which can be opened by the access key `keynum` to directory entry `dirolc`; the kinds of access allowed to wielder of `keynum` are defined by `obits`.

**DELKEY keynum dirolc** revokes privileges of access to the directory entry `dirolc` for holders of access key `keynum`.

**FRIENDP direct obiloc** if there is a permanent directory named `direct`, access to it is placed in `obiloc`; the access is highly restricted.

**FRIENDT direct obiloc** same as FRIENDP, except temporary directories.

**PCAP object** prints the indicated `object`.

**PDATA datum** prints `datum` words of data, starting at `datumloc`.

**MNEW object obiloc** places a link to `object` at `obiloc`.

**MDATA datum datumloc** moves `datum` to `datumloc`.

**CHAIN direct1 direct2** makes `direct2` look like an extension of `direct1`.

**UMCHAIN direct** eliminates any extension of `direct`.

**NEEV ident** creates a new variable `ident`.

**KILLV ident** eliminates the variable `ident`.

**DLIST direct** prints the contents of the directory `direct`.

**SPACE datum1 datum2 datum3 datum4** resources are reserved for the user; see section on space control.

**MSPACE direct1 datum** `direct2` `datum` sectors of disk space are moved from...
NEWU ident datum

direct1 to direct2. One must be the father of the other. (One sector=64 words)
creates new user subordinate to the user (i.e., a new permanent directory named ident
of size datum as a son of the user's permanent directory)

KILLU ident

the permanent directory ident is eliminated
from the user's permanent directory and
destroyed

NEWDR ident datum

creates a directory ident on the user's
permanent directory of size datum

NEWELK filadr
creates a new file block at filadr

KILLBLK filadr
deletes the file block at filadr

NEWKEY objloc
creates a new access key at objloc

KILLOBJ object
deletes the indicated object

DELLINK dirloc
removes the link at dirloc

direct1 to direct2. One must be the father

DELGNM dirloc

the ownership entry at dirloc is removed and
the owned object is destroyed

P.PULL
sets the print mode to print 20 successive
octal digits

P.ASCII
sets the print mode to print 60 bit words in
groups of 4,7,7,7,7,7,7,7, useful for deco-
ding text files which the user has somehow
been reduced to inspecting in octal

P.INST
sets the print mode to print octal digits in
groups of 15, useful for dumping code files
(this is the default mode)

IN.OCT
the mode of numbers typed into the Command
Processor complex is to be octal if not
expressly marked otherwise (this is the
default mode)

IN.DEC
the mode of numbers typed into the Command
Processor complex is to be decimal if not
expressly marked otherwise.
Parameters

Datum parameters are evaluated to 60-bit integers; notice that if the user gives the name of a datum, the datum is looked up for him.

Examples:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Represents</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>11</td>
<td>9, if 'IN.OCT'</td>
</tr>
<tr>
<td>11</td>
<td>11, if 'IN.DEC'</td>
</tr>
<tr>
<td>5+10-15D</td>
<td>-2, if 'IN.OCT'</td>
</tr>
<tr>
<td>VARIABLE+4</td>
<td>7, if VARIABLE contains 3</td>
</tr>
<tr>
<td>70B+(#52B+4)</td>
<td>56 plus the contents of cell 46 in the subsystem which just call the BEAD GHOST</td>
</tr>
</tbody>
</table>

Datumloc parameters specify places where data can be kept.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>A variable called 'NAME'</td>
</tr>
<tr>
<td>FILE#0</td>
<td>The first word of a file FILE in the Command Processor name space</td>
</tr>
<tr>
<td>#10</td>
<td>Cell 8 of the subprocess calling the BEAD GHOST</td>
</tr>
</tbody>
</table>

Direct parameters specify a directory.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>PERMDIR</td>
<td>The user's permanent directory</td>
</tr>
<tr>
<td>TEMPDIR</td>
<td>The user's temporary directory</td>
</tr>
<tr>
<td>USER:VV</td>
<td>The directory name 'VV' in the USER directory</td>
</tr>
<tr>
<td>USEB:VV:P</td>
<td>The directory named 'P' in the directory named 'VV' in the etc.</td>
</tr>
</tbody>
</table>

Dirloc parameters specify names of files in directories.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEMPDIR:INPUT</td>
<td>A file in the user's TEMPDIR</td>
</tr>
<tr>
<td>TEMPDIR:VV:REACT</td>
<td>A file in the directory named VV in the user's TEMPDIR</td>
</tr>
</tbody>
</table>

Filadr parameters specify addresses within files.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>INPUT#0</td>
<td>Word 0 of a file INPUT named in the Command Processor name space</td>
</tr>
<tr>
<td>TEMPDIR:VV:REACT#100</td>
<td>Word 64 of the file mentioned above</td>
</tr>
</tbody>
</table>

Fname is any legal file name; here are mentioned only strings of alphanumeric characters.

<table>
<thead>
<tr>
<th>Fname</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>INPUT</td>
<td></td>
</tr>
<tr>
<td>MYFILE10</td>
<td></td>
</tr>
</tbody>
</table>

Ident is again, any string of alphanumeric characters, blanks excluded.
**keynumb** is just a datum with a different name

301
VARIABLE

Access key number 301
Same, if VARIABLE = 301

**object** is a two-word set of information which is the internal form of stuff kept by the system, like files and directories and access keys; if the user specifies an **objloc**, the object will be fetched

OWN.KEY
SCANL

The user's private access key
The user's private name space

**objloc** parameters specify places where objects are kept, such as directories and variables

VARNAME
PERMDIR:FILENAME

The user can create a variable VARNAME and move objects to it
A dirloc is a special form of **objloc**

Time: 2-3PM  
Place: 201 Evans Hall  
Phone: (64)2-5817, to be changed to (64)2-5008 sometime soon

For the time being, I hope you will try to find out who you are talking to and how to contact him, as we don't know some of the people who are using the system. Please note each (coherent) contact with a customer in the 'Consultant's Log'. Who knows? We may identify some common problems that are correctable before the bookkeeping gets out of hand.

The only entertainment currently available on the system is ELIZA and REACT, both available in the directory USER:VV, password 'SIP'. Somebody is adapting his learning cubic program to the system, hopefully available soon.

AAP
18 NOV 71: 12:30 pm
CHRIS GRANGER CS1

Problem of understanding how to use RND(x) in BASIC.

Introduced him to use of RND(1) to cause real-time clock to be used as random number generator seed. Problem solved.
CAL Time-Sharing System
Status and Information, 19 October 1971

Schedule
CAL TSS will be run from 10:00 a.m. to 10:00 p.m. on weekdays. The hours from 12 to 6:00 will be reserved for customers. Customers who successfully login at other times may use the system at their own risk – they may be chased off on 5 minutes notice.

Consulting
A member of the CAL TSS staff is available from 2:00 to 3:00 p.m. on weekdays to answer questions, demonstrate the system, help new users through initial sessions, etc. The consultant will temporarily be located in Room 201, Evans Hall, (64)2-5817; to be changed to (64)2-5008.

Documentation, Information
The Introduction to CAL TSS, available from the Computer Center Library, hopefully provides a means of getting new users acquainted with CAL TSS. It also provides a good deal of information that may interest experienced users.

Charging
Free use of CAL TSS will end effective 25 October 1971. Arrangements can be made now with the Computer Center Accounting Office; (64)2-7355, 237 Evans Hall to have TSS funds available on the 25th, thus avoiding any interruption in your service. Please note that even if you have a valid Computer Center job number, you must still file another form to make those funds available on TSS.

Details of the rate structure are appended.

Teletypes
All teletypes connected to the system as of 18 September should be functioning as before. Report all line problems and problems with Computer Center teletypes to Gil Costa, (64)2-4775. Some details specifying the problem will be required.

Access to Teletypes
The TTYs which were available for general use in 225 Campbell has disappeared in the machine shuffle. Some TTYs are being installed in B30 Evans Hall, but the use of these TTYs will be subject to some control not as yet specified. It will also be a week or more before these TTYs are connected at all. If this interferes with your access to the system, please contact the CAL TSS consultant and make the details of your problem known to him.
Availability

CAL TSS is currently available weekdays from 2-6 PM. There are 8 teletypes available for general use during these hours in Rooms 225 and 223 Campbell Hall. For information about connection of additional teletypes, contact Vance Vaughan (see below).

Documentation

The fundamental document for users is the Introduction to CAL TSS, available from the Computer Center librarian. Other documentation is also available at the library, but it is spotty and users should consult with someone on the TSS staff before acquiring any.

TSS Consultant

A member of the TSS staff is available in Room 225 Campbell Hall, ext. 2-5008, from 2-3 PM every weekday except Wednesday. He will answer questions, demonstrate the system, help new users through initial sessions, etc. Users unable to reach the consultant should contact Vance Vaughan, 207 Evans Hall, ext. 2-5823. He is there Thursdays from 1-2 PM, or by accident, or by appointment. Leave a message in the main Computer Center office, 239 Evans Hall, ext. 2-0851 to arrange an appointment.

Getting help, reporting problems, etc.

Sections 1.7 and 1.9 of the Introduction to CAL TSS give procedures and information for diagnosing and understanding problems encountered when using the system. If the user's teletype is dead, or has gone crazy, he should first consult those sections. They may solve the problem, or be irrelevant, or give some such helpful advice as 'call a system programmer' or 'the teletype is down or the system is down'. If they are irrelevant, or say to contact a system programmer, or something like that, contact the TSS consultant (not the regular programming consultant). When the diagnosis is that the teletype is down or the system is down, the user should call the shift supervisor, (64)2-3043, and explain the problem. If the system is down, he will give information about when it will be up. If the system is up, there is some problem with the teletype or the line. The user should contact the person responsible for the maintainence of the teletype (Computer Center teletypes are maintained by Charles Cuffel, ext. 2-4403).

Complaints and suggestions:

These should be made to the TSS consultant. The TSS staff is especially anxious to get feedback on the documentation. Corrections to content and suggested style modifications are both welcome.
How to find the teletype watcher in a PM dump.

This involves finding the special event channel that the watcher hangs on and looking at its queueing word. The MOT of the watcher doesn't change unless initialization changes, so noting the most recent MOT will shortcut this procedure in most cases.

1. Find the MOT and print the first few cells. The beginning of the MOT is given by the symbol EC.MOT, defined in the deck ECSINIT in the ECS system. It hardly ever changes. Currently = 411B

2. Two items are of interest: unique name 2 is the master C-list unique name 3 is the interrupt object file. Print the address specified for the interrupt object file. The very first word contains a pointer to the data block, usually just a few dells down from the file header itself. Print the first word of the data block. This is the index in the master c-list of the event channel where the watcher hangs.

3. Take the address of the master c-list from the MOT, add 1 and add the index of the watcher's event channel twice to find the address of the watchers event channel stuff. Print 3 capabilities (6 words) starting at that address. You should find a file followed by two evchs. The 1st evch is where the watcher hangs. Print its MOT slot.

4. Use the MOT pointer you just found to print the first two words of the evch. The second word is the process queueing word. If it starts with 1776, the watcher wasn't hanging when the dump was taken, sorry. Otherwise, the low 6 digits of the word are the MOT of the watcher. Congratulations.

5. A second page on how to find the user processes, given the wx location of the watcher, is forthcoming. That may be even more fun.
