

AB's Mark III

~ Feb '71

Move Δ Donation $\left\{ \begin{array}{l} + \text{ if father donos} \\ - \text{ if son donos} \end{array} \right.$

C: Donos
C: Donos
D: donation ≥ 0

Father in use \leftarrow in use $+\Delta$
son res \leftarrow res $+\Delta$
son chrg \leftarrow chrg $+\Delta$ } if resulting res \geq ~~res~~ in use

Steal C: donos
C: donee
C: common ancestor
D: steal ≥ 0

donos in use \leftarrow in use $+\Delta$ (if still \leq res)
donee in use \leftarrow in use $-\Delta$

Destroy AB: current algorithm +
if in use $\neq 0$, add to father in use

- Known effects:
- 1) No more consistency check (in use $= 0$ at destruction no longer true)
 - 2) AB may disappear out from under dich (which then does what?)
 - 3) User can have operation ^{to be changed}
 - 4) User can't prevent AB to disk system

with current D.V implementation, steal impossible at that level
(verification of common ancestor impossible)
